ABSTRACT. This is a complement to my previous article “Advanced Determinant Calculus” (Séminaire Lotharingien Combin. 42 (1999), Article B42q, 67 pp.). In the present article, I share with the reader my experience of applying the methods described in the previous article in order to solve a particular problem from number theory (G. Almkvist, J. Petersson and the author, Experiment. Math. 12 (2003), 441–456). Moreover, I add a list of determinant evaluations which I consider as interesting, which have been found since the appearance of the previous article, or which I failed to mention there, including several conjectures and open problems.

1. Introduction

In the previous article [103], I described several methods to evaluate determinants, and I provided a long list of known determinant evaluations. The present article is meant as a complement to [103]. Its purpose is three-fold: first, I want to shed light on the problem of evaluating determinants from a slightly different angle, by sharing with the reader my experience of applying the methods from [103] in order to solve a particular problem from number theory (see Sections 3 and 4); second, I shall address the question why it is apparently in the first case combinatorialists (such as myself) who are so interested in determinant evaluations and get so easily excited about them (see Section 2); and, finally third, I add a list of determinant evaluations, which I consider as interesting, which have been found since the appearance of [103], or which I

Key words and phrases. Determinants, Vandermonde determinant, Cauchy’s double alternant, skew circulant matrix, confluent alternant, confluent Cauchy determinant, Pfaffian, Hankel determinants, orthogonal polynomials, Chebyshev polynomials, Meixner polynomials, Laguerre polynomials, continued fractions, binomial coefficient, Catalan numbers, Fibonacci numbers, Bernoulli numbers, Stirling numbers, non-intersecting lattice paths, plane partitions, tableaux, rhombus tilings, lozenge tilings, alternating sign matrices, non-crossing partitions, perfect matchings, permutations, signed permutations, inversion number, major index, compositions, integer partitions, descent algebra, non-commutative symmetric functions, elliptic functions, the number π, LLL-algorithm.

failed to mention in the list given in Section 3 of [103] (see Section 5), including several conjectures and open problems.

2. Enumerative combinatorics, nice formulae, and determinants

Why are combinatorialists so fascinated by determinant evaluations?

A simplistic answer to this question goes as follows. Clearly, binomial coefficients \( \binom{n}{k} \) or Stirling numbers (of the second kind) \( S(n,k) \) are basic objects in (enumerative) combinatorics; after all they count the subsets of cardinality \( k \) of a set with \( n \) elements, respectively the ways of partitioning such a set of \( n \) elements into \( k \) pairwise disjoint non-empty subsets. Thus, if one sees an identity such as\(^1\)

\[
\det_{1\leq i,j\leq n} \left( \begin{array}{c} a + b \\ a - i + j \end{array} \right) = \prod_{i=1}^{n} \frac{(a + b + i - 1)! (i - 1)!}{(a + i - 1)! (b + i - 1)!},
\]

or\(^2\)

\[
\det_{1\leq i,j\leq n} (S(i + j, i)) = \prod_{i=1}^{n} i^i
\]

(and there are many more of that kind; see [103] and Section 5), there is an obvious excitement that one cannot escape.

Although this is indeed an explanation which applies in many cases, there is also an answer on a more substantial level, which brings us to the reason why I like (and need) determinant evaluations.

The *favourite question* for an enumerative combinatorialist (such as myself) is

*How many \( \ldots \) are there?*

Here, \( \ldots \) can be permutations with certain properties, certain partitions, certain paths, certain trees, etc. The *favourite theorem* then is:

**Theorem 1.** The number of \( \ldots \) of size \( n \) is equal to \[ \text{NICE}(n). \]

I have already explained the meaning of \( \ldots \). What does \( \text{NICE}(n) \) stand for? Typical examples for \( \text{NICE}(n) \) are formulae such as

\[
\frac{1}{n+1} \binom{2n}{n}
\]

(*Catalan numbers*, cf. [170, Ex. 6.19]) or

\[
\prod_{i=0}^{n-1} \frac{(3i + 1)!}{(n + i)!}
\]

\(^1\)For more information on this determinant see Theorems 2 and 4 in this section and [103, Sections 2.2, 2.3 and 2.5].

\(^2\)This determinant evaluation follows easily from the matrix factorisation

\[
(S(i + j, i))_{1\leq i,j\leq n} = ((-1)^{k} k!/(k! (i - k)!))_{1\leq i,k\leq n} \cdot (k!)_{1\leq k,j\leq n},
\]

application of [103, Theorem 26, (3.14)] to the first determinant, and application of the Vandermonde determinant evaluation to the second.
(the number of $n \times n$ alternating sign matrices and several other combinatorial objects; cf. [27]). Let us be more precise.

**Definition.** The symbol $NICE(n)$ is a formula of the type

$$
\xi^n \cdot \text{Rat}(n) \cdot \prod_{i=1}^{k} \frac{(a_in + b_i)!}{(c_in + d_i)!},
$$

where $\text{Rat}(n)$ is a rational function in $n$, and where $a_i, c_i \in \mathbb{Z}$ for $i = 1, 2, \ldots, k$, $\mathbb{Z}$ denoting the set of integers. The parameters $b_i, c_i, \xi$ can be arbitrary real or complex numbers. (If necessary, $(a_in + b_i)!$ has to be interpreted as $\Gamma(a_in + b_i + 1)$, where $\Gamma(x)$ is the Euler gamma function, and similarly for $(c_in + d_i)!$.)

Clearly, the formulae (2.3) and (2.4) fit this “Definition”.³

If one is working on a particular problem, how can one recognise that one is looking at a sequence of numbers given by $NICE(n)$? The key observation is that, if we factorise $(an + b)!$ into its prime factors, where $a$ and $b$ are integers, then, as $n$ runs through the positive integers, the numbers $(an + b)!$ explode quickly, whereas the prime factors occurring in the factorisation will grow only moderately, more precisely, they will grow roughly linearly. Thus, if we encounter a sequence the prime factorisation of which has this property, we can be sure that there is a formula $NICE(n)$ for this sequence. Even better, as I explain in Appendix A of [103], the program Rate⁴ will (normally⁵) be able to guess the formula.

To illustrate this, let us look at a particular example. Let us suppose that the first few values of our sequence are the following:

1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, 208012, 742900, 2674440, 9694845, 35357670, 129644790, 477638700, 1767263190, 6564120420.

The prime factorisation of the second-to-last number is (we are using Mathematica here)

In[1]:= FactorInteger[477638700]

³The writing $NICE(n)$ is borrowed from Doron Zeilberger [185, Recitation III]. The technical term for a formula of the type (2.5) is “hypergeometric term”, see [136, Sec. 3.2], whereas, most often, the colloquial terms “closed form” or “nice formula” are used for it, see [185, Recitation II]. More recently, some authors call sequences given by formulae of that type sequences of “round” numbers, see [111, Sec. 6].

⁴Rate is available from http://igd.univ-lyon1.fr/~kratt. It is based on a rather simple algorithm which involves rational interpolation. In contrast to what I read, with great surprise, in [43], the explanations of how Rate works in Appendix A of [103] can be read and understood without any knowledge about determinants and, in particular, without any knowledge of the fifty or so pages that precede Appendix A in [103].

⁵Rate will always be able to guess a formula of the type (2.5) if there are enough initial terms of the sequence available. However, there is a larger class of sequences which have the property that the size of the primes in the prime factorisation of the terms of the sequence grows only slowly with $n$. These are sequences given by formulae containing “Abelian” factors, such as $n^n$. Unfortunately, Rate does not know how to handle such factors. Recently, Rubey [150] proposed an algorithm for covering Abelian factors as well. His implementation Guess is written in Axiom and is available at http://www.mat.univie.ac.at/~rubey/martin.html.
Out[1] = {{2, 2}, {3, 1}, {5, 2}, {7, 1}, {11, 1}, {23, 1}, {29, 1}, {31, 1}}

whereas the prime factorisations of the next-to-last and the last number in this sequence are

In[2] := FactorInteger[1767263190]
Out[2] = {{2, 1}, {3, 1}, {5, 1}, {7, 1}, {11, 1}, {23, 1}, {29, 1}, {31, 1},
> {37, 1}}

In[3] := FactorInteger[6564120420]
Out[3] = {{2, 2}, {3, 1}, {5, 1}, {11, 1}, {13, 1}, {23, 1}, {29, 1}, {31, 1},
> {37, 1}}

(To decipher this for the reader unfamiliar with Mathematica: the prime factorisation of the last number is $2^23^15^111^113^123^129^131^137^1$.) One observes, first of all, that the occurring prime factors are rather small in comparison to the numbers of which they are factors, and, second, that the size of the prime factors grows only very slowly (from 31 to 37). Thus, we can be sure that there is a “nice” formula $NICE(n)$ for this sequence. Indeed, Rate needs only the first five members of the sequence to come up with a guess for $NICE(n)$:

In[4] := <<rate.m
In[5] := Rate[1, 2, 5, 14, 42]

\begin{align*}
& 10 \\
& 4 \quad \text{Gamma}[- + i0] \\
& 2 \\
\end{align*}

Out[5] = \text{-------------------} \\
\text{Sqrt[Pi] Gamma[2 + i0]}

As the reader will have guessed, Rate uses the parameter $i0$ instead of $n$. In fact, the formula is a fancy way to write $\frac{1}{\text{Sqrt[Pi] Gamma[2 + i0]}}$, that is, we were looking at the sequence of Catalan numbers (2,3).

To see the sharp contrast, here are the first few terms of another sequence:

$$1, 2, 9, 272, 589185.$$  

(Also these are combinatorial numbers. They count the perfect matchings of the $n$-dimensional hypercube; cf. [138, Problem 19].) Let us factorise the last two numbers:

Out[6] = {{2, 4}, {17, 1}}

In[7] := FactorInteger[589185]
Out[7] = {{3, 2}, {5, 1}, {13093, 1}}

The presence of the big prime factor 13093 in the last factorisation is a sure sign that we cannot expect a formula $NICE(n)$ as described in the “Definition” for this sequence of numbers. (There may well be a simple formula of a different kind. It is not very likely, though. In any case, such a formula has not been found up to this date.)
Now, that I have sufficiently explained all the ingredients in the “prototype theorem” Theorem 1, I can explain why theorems of this form are so attractive (at least to me): the objects (i.e., the permutations, partitions, paths, trees, etc.) that it deals with are usually very simple to explain, the statement is very simple and can be understood by anybody, the result $NICE(n)$ has a very elegant form, and yet, very often it is not easy at all to give a proof (not to mention a true explanation why such an elegant result occurs.)

Here are two examples. They concern rhombus tilings, by which I mean tilings of a region by rhombi with side lengths 1 and angles of 60° and 120°. The first one is a one century old theorem due to MacMahon [123, Sec. 429, $q \to 1$; proof in Sec. 494].

**Theorem 2.** The number of rhombus tilings of a hexagon with side lengths $a, b, c, a, b, c$ whose angles are 120° (see Figure 1.a for an example of such a hexagon, and Figure 1.b for an example of a rhombus tiling) is equal to

$$\prod_{i=1}^{c} \frac{(a + b + i - 1)!(i - 1)!}{(a + i - 1)!(b + i - 1)!}.$$  

(2.6)

![Diagram of a hexagon and a rhombus tiling](image)

**Figure 1**

To be correct, MacMahon did not know anything about rhombus tilings, they did not exist in enumerative combinatorics at the time. The objects that he considered were plane partitions. However, there is a very simple bijection between plane partitions contained in an $a \times b \times c$ box and rhombus tilings of a hexagon with side lengths $a, b, c, a, b, c$, as explained for example in [48].
The second one is more recent, and is due to Ciucu, Eisenkölbl, Zare and the author [37, Theorem 1].

**Theorem 3.** If $a,b,c$ have the same parity, then the number of lozenge tilings of a hexagon with side lengths $a, b, c, a + m, b, c + m$, with an equilateral triangle of side length $m$ removed from its centre (see Figure 2 for an example) is given by

$$
\frac{H(a + m) H(b + m) H(c + m) H(a + b + c + m) H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor) H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor)}{H(a + b + m) H(a + c + m) H(b + c + m) H(\frac{a+b}{2} + m) H(\frac{a+c}{2} + m) H(\frac{b+c}{2} + m)}
\times
\frac{H(m + \left\lfloor \frac{a}{2} \right\rfloor) H(m + \left\lfloor \frac{b}{2} \right\rfloor) H(m + \left\lfloor \frac{c}{2} \right\rfloor)}{H(m + \left\lfloor \frac{a+b}{2} \right\rfloor) H(m + \left\lfloor \frac{a+c}{2} \right\rfloor) H(m + \left\lfloor \frac{b+c}{2} \right\rfloor)}
\times
\frac{H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor) H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor)}{H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor) H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor) H(m + \left\lfloor \frac{a+b+c}{2} \right\rfloor) H(\frac{a+b+c}{2}) H(\frac{a+b+c}{2})},
$$

(2.7)

where

$$
H(n) := \begin{cases} 
\prod_{k=0}^{n-1} \Gamma(k + 1) & \text{for } n \text{ an integer}; \\
\prod_{k=0}^{\frac{n}{2}} \Gamma(k + \frac{1}{2}) & \text{for } n \text{ a half-integer.}
\end{cases}
$$

(2.8)

(There is a similar theorem if the parities of $a,b,c$ should not be the same, see [37, Theorem 2]. Together, the two theorems generalise MacMahon’s Theorem 2.)

The reader should notice that the right-hand side of (2.6) is indeed of the form $NICE(a)$, while the right-hand side of (2.7) is of the form $NICE(m/2)$.

Where is the connexion to determinants? As it turns out, these two theorems are in fact **determinant evaluation theorems**. More precisely, Theorem 2 is equivalent to the following theorem.\(^7\)

\(^7\)Bijective proofs of Theorem 2 which “explain” the “nice” formula are known [100, 102]. I do not ask for a bijective proof of Theorem 3 because I consider the task of finding one as daunting.
Theorem 4. 
\[
\det_{1 \leq i, j \leq c} \left( \begin{array}{c}
\begin{array}{c}
a + b \\
a - i + j
\end{array}
\end{array} \right) = \prod_{i=1}^{c} \frac{(a + b + i - 1)! (i - 1)!}{(a + i - 1)! (b + i - 1)!}.
\]
(2.9) 

(The reader should notice that this is exactly (2.1) with \( n \) replaced by \( c \).) On the other hand, Theorem 3 is equivalent to the theorem below.\(^8\)

Theorem 5. If \( m \) is even, the determinant
\[
\det_{1 \leq i, j \leq a+m} \left( \begin{array}{c}
\begin{array}{c}
b + c + m \\
b - i + j
\end{array}
\end{array} \right) \quad \text{1} \leq i \leq a
\]
\[
\begin{array}{c}
\begin{array}{c}
b + \frac{c}{2} \\
a + 1 \leq i \leq a + m
\end{array}
\end{array}
\]
(2.10) 
is equal to \( (2.7) \). \( \square \)

The link between rhombus tilings (and equivalent objects such as plane partitions, semistandard tableaux, etc.) and determinants which explains the above two equivalence statements is non-intersecting lattice paths.\(^9\) The latter are families of paths in a lattice with the property that no two paths in the family have a point in common. Indeed, rhombus tilings are (usually) in bijection with families of non-intersecting paths in the integer lattice \( \mathbb{Z}^2 \) which consist of unit horizontal and vertical steps. (Figure 3 illustrates the bijection for the rhombus tilings which appear in Theorem 3 in an example. In that bijection, all horizontal steps of the paths are in the positive direction, and all vertical steps are in the negative direction. See the explanations that accompany [37, Figure 8] for a detailed description. Since, as I explained, Theorem 3 essentially is a generalization of Theorem 2, this gives also an idea for the bijection for the rhombus tilings which appear in the latter theorem. For other instances of bijections between rhombus tilings and non-intersecting lattice paths see [38, 40, 41, 52, 53, 54, 57, 106, 133].) In the case that the starting points and the end points of the lattice paths are fixed, the following many-author-theorem applies.\(^10\)

\(^8\)To be correct, this is a little bit oversimplified. The truth is that equivalence holds only if \( m \) is even. An additional argument is necessary for proving the result for the case that \( m \) is odd. We refer the reader who is interested in these details to [37, Sec. 2].

\(^9\)There exists in fact a second link between rhombus tilings and determinants which is not less interesting or less important. It is a well-known fact that rhombus tilings are in bijection with perfect matchings of certain hexagonal graphs. (See for example [110, Figures 13 and 14].) In view of this fact, this second link is given by Kasteleyn's theorem [92] saying that the number of perfect matchings of a planar graph is given by the Pfaffian of a slight perturbation of the adjacency matrix of the graph. See [110] for an exposition of Kasteleyn's result, including historical notes, and for adaptations taking symmetries of the graph into account.

\(^10\)This result was discovered and rediscovered several times. In a probabilistic form, it occurs for the first time in work by Karlin and McGregor [90, 91]. In matroid theory, it is discovered in its discrete form by Lindström [118, Lemma 1]. Then, in the 1980s the theorem is rediscovered at about the same time in three different communities, not knowing from each other at the time: in statistical physics by Fisher [58, Sec. 5.3] in order to apply it to the analysis of vicious walkers as a model of wetting and melting, in combinatorial chemistry by John and Sachs [85] and Gronau, Just, Schade, Scheffler and Wojciechowski [72] in order to compute Pauling's bond order in benzoid hydrocarbon molecules, and in enumerative combinatorics by Gessel and Viennot [67, 68] in order to count tableaux and plane
a. A lozenge tiling of the cored hexagon in Figure 2  

b. The corresponding path family

c. The path family made orthogonal

**Figure 3**

**Theorem 6** (Karlin–McGregor, Lindström, Gessel–Viennot, Fisher, John–Sachs, Gronau–Just–Schäde–Scheffler–Wojciechowski). Let $A_1, A_2, \ldots, A_n$ and $E_1, E_2, \ldots, E_n$ be lattice points such that for $i < j$ and $k < l$ any lattice path between $A_i$ and $E_l$ has a common point with any lattice path between $A_j$ and $E_k$. Then the number of all families $(P_1, P_2, \ldots, P_n)$ of non-intersecting lattice paths, $P_i$ running from $A_i$ to $E_i$, $i = 1, 2, \ldots, n$, is given by

$$\det_{1 \leq i, j \leq n} \left( P(A_j \rightarrow E_i) \right),$$

where $P(A \rightarrow E)$ denotes the number of all lattice paths from $A$ to $E$.

It goes beyond the scope of this article to include the proof of this theorem here. However, I cannot help telling that it is an extremely beautiful and simple proof that

partitions. Since only Lindström, and then Gessel and Viennot state the result in its most general form (not reproduced here), I call this theorem most often the “Lindström–Gessel–Viennot theorem.” It must be also mentioned that the so-called “Slater determinant” in quantum mechanics (cf. [162] and [163, Ch. 11]) may qualify as an “ancestor” of the Lindström–Gessel–Viennot determinant.
every mathematician should have seen once, even if (s)he does not have any use for it in her/his own research. I refer the reader to [67, 68, 171].

Now the origin of the determinants becomes evident. In particular, since, for rhombus tilings, we have to deal with lattice paths in the integer lattice consisting of unit horizontal and vertical steps, and since the number of such lattice paths which connect two lattice points is given by a binomial coefficient, we see that the enumeration of rhombus tilings must be a rich source for binomial determinants. This is indeed the case, and there are several instances in which such determinants can be evaluated in the form \( NICE(.) \) (see [35, 37, 38, 40, 41, 52, 53, 54, 57, 65, 103] and Section 5). Often the evaluation part is highly non-trivial.

The evaluation of the determinant (2.9) is not very difficult (see [103, Sections 2.2, 2.3, 2.5] for 3 different ways to evaluate it). On the other hand, the evaluation of the determinant (2.10) requires some effort (see [37, Sec. 7]).

To conclude this section, I state another determinant evaluation, to which I shall come back later. Its origin lies as well in the enumeration of rhombus tilings and plane partitions (see [99, Theorem 10] and [39, Theorem 2.1]).

**Theorem 7.** For any complex numbers \( x \) and \( y \) there holds

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{(x + y + i + j - 1)!}{(x + 2i - j)!(y + 2j - i)!} \right) = \prod_{i=0}^{n-1} \frac{4!(x + y + i - 1)!(2x + y + 2i)_i(x + 2y + 2i)_i}{(x + 2i)!(y + 2i)!},
\]

where the shifted factorials or Pochhammer symbols \((a)_k\) are defined by \((a)_k := a(a + 1)\cdots(a + k - 1), \ k \geq 1, \ \text{and} \ (a)_0 := 1. \ \text{(In this formula, a factorial \( m! \) has to be interpreted as \( \Gamma(m + 1) \) if \( m \) is not a non-negative integer.)}

3. A determinant from number theory

However, determinants do not only arise in combinatorics, they also arise in other fields. In this section, I want to present a determinant which arose in number theory, explain in some detail its origin, and then outline the steps which led to its evaluation, thereby giving the reader an opportunity to look "behind the scenes" while one tries to make the determinant evaluation methods described in [103] work.

The story begins with the following two series expansions for \( \pi \). The first one is due to Bill Gosper [71],

\[
\pi = \sum_{n=0}^{\infty} \frac{50n - 6}{(3n)_n^2 2^n},
\]

and was used by Fabrice Bellard [20, file `pi1.c` to find an algorithm for computing the \( n \)-th decimal of \( \pi \) without computing the earlier ones, thus improving an earlier algorithm due to Simon Plouffe [137]. The second one,

\[
\pi = \frac{1}{740025} \left( \sum_{n=1}^{\infty} \frac{3P(n)^2}{(2n)_n^2 2^{n-1}} - 20379280 \right),
\]

\( 3P(n) \) is the \( 3 \)-th power of the \( n \)-th number in the list of numbers ordered by their absolute value.
where
\[
P(n) = -885673181n^5 + 3125347237n^4 - 2942969225n^3 \\
+ 1031962795n^2 - 196882274n + 10996648,
\]
is due to Fabrice Bellard [20], and was used by him in his world record setting computation of the 1000 billionth binary digit of \( \pi \), being based on the algorithm in [19].

Going beyond that, my co-authors from [5], Gert Almkvist and Joakim Peterson, asked themselves the following question:

_Are there more expansions of the type_

\[
\pi = \sum_{n=0}^{\infty} \frac{S(n)}{(\frac{m}{pn})a^n},
\]

_where \( S(n) \) is some polynomial in \( n \) (depending on \( m, p, a \))?_

How can one go about to get some intuition about this question? One chooses some specific \( m, p, a \), goes to the computer, computes

\[
p(k) = \sum_{n=0}^{\infty} \frac{n^k}{(\frac{m}{pn})a^n}
\]
to many, many digits for \( k = 0, 1, 2, \ldots \), puts

\[
\pi, p(0), p(1), p(2), \ldots
\]

into the LLL-algorithm (which comes, for example, with the Maple computer algebra package), and one waits whether the algorithm comes up with an integral linear combination of \( \pi, p(0), p(1), p(2), \ldots \).\(^{11}\) Indeed, Table 1 shows the parameter values, where the LLL-algorithm gave a result.

For example, it found

\[
\pi = \frac{1}{r} \sum_{n=0}^{\infty} \frac{S(n)}{(\frac{m}{pn})^{16^n}},
\]

where

\[
r = 3^6 5^3 2^2 11^2 13^2
\]

and

\[
S(n) = -869897157255 - 3524219363487888n + 112466777263118189n^2 \\
- 1242789726208374386n^3 + 6693196178751930680n^4 - 19768094496651298112n^5 \\
+ 32808347163463348736n^6 - 28892659596072587264n^7 + 1053050748472012800n^8,
\]

\(^{11}\)For readers unfamiliar with the LLL-algorithm: in this particular application, it takes as an input rational numbers \( r_1, r_2, \ldots, r_m \) (which, in our case, will be the numbers 1 and the rational approximations of \( \pi, p(0), p(1), \ldots \) which we computed), and, if successful, outputs _small_ integers \( c_1, c_2, \ldots, c_m \) such that \( c_1 r_1 + c_2 r_2 + \cdots + c_m r_m \) is very _small_. Thus, if \( r_i \) was a good approximation for the real number \( x_i, i = 1, 2, \ldots, m \), one can expect that actually \( c_1 x_1 + c_2 x_2 + \cdots + c_m x_m = 0 \). See [115, Sec. 1, in particular the last paragraph] and [42, Ch. 2] for the description of and more information on this important algorithm. In particular, also here, the output of the algorithm (if there is) is just a (very guided) _guess_. Thus, a proof is still needed, although the probability that the guess is wrong is infinitesimal. As a matter of fact, it is very likely that Bellard had no proof of his formula (3.2) …

**Table 1**
\[ \pi = \sum_{n=0}^{\infty} \frac{S_k(n)}{\binom{4kn}{kn}} (-4)^{kn}, \]

where \( S_k(n) \) is some polynomial in \( n \) of degree \( 4k \).

In order to make progress on this observation, we have to first see how one can prove such an identity, once it is found. In fact, this is not difficult at all. To illustrate the idea, let us go through a proof of Gosper’s identity (3.1).

The beta integral evaluation (cf. [12, Theorem 1.1.4]) gives

\[ \frac{1}{\binom{3n}{n}} = (3n + 1) \int_0^1 x^{2n} (1-x)^n \, dx. \]

Hence the right hand side of the formula will be

\[ \int_0^1 \sum_{n=0}^{\infty} \frac{(50n - 6)(3n + 1)}{n!} \left( \frac{x^2(1-x)}{2} \right)^n \, dx. \]

We have

\[ \sum_{n=0}^{\infty} \frac{(50n - 6)(3n + 1)y^n}{n!} = \frac{2(56y^2 + 97y - 3)}{(1-y)^3}. \]  (3.3)

Thus, if substituted, we obtain

\[ \text{RHS} = 8 \int_0^1 \frac{28x^6 - 56x^5 + 28x^4 - 97x^3 + 97x^2 - 6}{(x^3 - x^2 + 2)^3} \, dx \]

\[ = \left[ \frac{4x(x-1)(x^3 - 28x^2 + 9x + 8)}{(x^3 - x^2 + 2)^2} + 4 \arctan(x-1) \right]_0^1 = \pi. \]  (3.4)

(Clearly, both (3.3) and (3.4) are routine calculations, and therefore we did not do it by hand, but let them be worked out by Maple.)

Now let us fix \( k \geq 1 \). We apply the same procedure to \( \sum_{n=0}^{\infty} \frac{S_k(n)}{\binom{4kn}{kn}} (-4)^{kn}, \) where \( S_k(n) \) is (hopefully) some (unknown) polynomial in \( n \). The beta integral evaluation gives

\[ \frac{1}{\binom{4kn}{kn}} = (8kn + 1) \int_0^1 x^{4kn} (1-x)^{4kn} \, dx. \]

Hence, if \( S_k(n) \) should have degree \( d \) in \( n \),

\[ \sum_{n=0}^{\infty} \frac{S_k(n)}{\binom{4kn}{kn}} (-4)^{kn} = \int_0^1 \sum_{n=0}^{\infty} \frac{(8kn + 1)S_k(n)}{\binom{4kn}{kn}} \left( \frac{x^{4k}(1-x)^{4k}}{(-4)^{kn}} \right)^n \, dx \]

\[ = \int_0^1 \frac{P_k(x)}{(x^{4k}(1-x)^{4k} - (-4)^k)^{d+2}} \, dx, \]  (3.5)
where \( P_k(x) \) is some polynomial in \( x \). For convenience, let us write \( P \) as a short-hand for \( P_k \). Let \( Q(x) := x^k (1 - x)^k - (-4)^k \). Now we make the wild assumption that

\[
\int \frac{P(x)}{Q(x)^{d+2}} \, dx = \frac{R(x)}{Q(x)^{d+1}} + 2 \arctan(x) + 2 \arctan(x - 1),
\]

for some polynomial \( R(x) \) with \( R(0) = R(1) = 0 \). Then the original sum would indeed be equal to \( \pi \). The last equality is equivalent to

\[
P \frac{Q}{Q^{d+2}} = \frac{R}{Q^{d+1}} - (d + 1) \frac{QR}{Q^{d+2}} + 2 \left( \frac{1}{x^2 + 1} + \frac{1}{x^2 - 2x + 2} \right),
\]

or

\[
QR' - (d + 1)Q'R = P - 2Q^{d+2} \left( \frac{1}{x^2 + 1} + \frac{1}{x^2 - 2x + 2} \right).
\]

In our examples, we observed that

\[
R(x) = (2x - 1) \hat{R}(x(1 - x))
\]

for a polynomial \( \hat{R} \). So, let us make the substitution

\[
t = x(1 - x).
\]

Then, after some simplification, the above differential equation becomes

\[
-(1 - 4t)Q \frac{d \hat{R}}{dt} + (2Q + 4k(4k + 1)(1 - 4t)t^{k-1}) \hat{R} - P + 2(3 - 2t) \frac{Q_{1k+2}}{t^2 - 2t + 2} = 0, \tag{3.6}
\]

where \( Q(t) = t^k - (-4)^k \).

Now, writing \( N(k) = 4k(4k + 1) \), we make the Ansatz

\[
\hat{R}(t) = \sum_{j=1}^{N(k)-1} a(j)t^j,
\]

\[
S_k(n) = \sum_{j=0}^{4k} a(N(k) + j)n^j.
\]

(The reader should recall that \( S_k(n) \) defines \( P_k(t) = P(t) \) through (3.5).) Comparing coefficients of powers of \( t \) on both sides of (3.6), we get a system of \( N(k) + 4k \) linear equations for the unknowns \( a(1), a(2), \ldots, a(N(k) + 4k) \).

Hence: If the determinant of this system of linear equations is non-zero, then there does indeed exist a representation

\[
\pi = \sum_{n=0}^{\infty} \frac{S_k(n)}{(8kn)(-4)^n}.
\]

To see whether we could indeed hope for the determinant to be non-zero, we went again to the computer and looked at the values of the determinant in some small instances. (Obviously, we do not want to do this by hand, since for \( k = 1 \) the matrix is already a 24x24 matrix!) So, let us program the matrix. (We shall see the mathematical definition of the matrix in just a moment, see (3.8).\textsuperscript{12})

\textsuperscript{12}To tell the truth, this is the form of the matrix after some simplifications have already been carried out. (In particular, we are looking at a matrix which is slightly smaller than the original one.) See [5, beginning of Section 4] for these details. There, the matrix in (3.8) is called \( M''' \).
\textbf{In[8]} := \texttt{a[k_\_j_] := Module\{\text{Var} = j/(4k)\},
\quad \text{(1)} \times (\text{Var} - 1) \times 8k(4k + 1)(-4)^k(\text{Var} + 1) \times
\quad \text{Product}[4k \times 1 - 1,\{1, 1, 4k - \text{Var}\}] \times \text{Product}[4k \times 1 + 1,\{1, 1, \text{Var} - 1\}]\}
\text{]
\text{In[9]} := \texttt{A[k_\_i_\_j_] := Module\{\text{Var}\},
\quad \text{Var} = \{\text{Floor}[(i - 2)/(4k - 1)]\},
\quad \text{Floor}[(j - 1)/(4k)], \text{Mod}[i - 2, 4k - 1],
\quad \text{Mod}[j - 1, 1], 4k]\};
\quad \text{If}[i = 1,
\quad \text{If}[\text{Mod}[j, 4k] = 0, \text{a[k, j], 0}],
\quad \text{If}[\text{Var}[1] - \text{Var}[2] = 0,
\quad \text{Switch}[\text{Var}[3] - \text{Var}[4], 0, \text{f1[k], \text{Var}[3] + 1, j], -1,
\quad \text{f0[k], \text{Var}[3] + 1, j], 0, 0],
\quad \text{If}[\text{Var}[1] - \text{Var}[2] = 1,
\quad \text{Switch}[\text{Var}[3] - \text{Var}[4], 0, \text{g1[k], \text{Var}[3] + 1, j], 1,
\quad \text{g0[k], \text{Var}[3] + 1, j], 0, 0]]\}
\text{In[10]} := \texttt{A[k_\_] := Table[A[k, i, j],\{i, 1, 16k^2\},\{j, 1, 16k^2\}]}
\text{In[11]} := \texttt{f0[k_\_i_\_j_] := j \times (-4)^k;
\quad f1[k_\_i_\_j_] := -(2 + 4)^k \times (-4)^k;
\quad g0[k_\_i_\_j_] := (4k \times (4k + 1) - j);
\quad g1[k_\_i_\_j_] := (-4 \times 4k \times (4k + 1) + 2 + 4j)}

We shall not try to digest this at this point. Let us accept the program as a black box, and let us compute the determinant for \textit{k = 2}.

\text{In[12]} := \texttt{Det[A[2]]}
\text{Out[12]} = -601576375580370166777074138698518196031142518971568946712\>
\quad \quad \quad 2204136674781038302774231725971306459064075121023092662279814\>
\quad \quad \quad 015195545600000000000

Magnificent! This is certainly \textit{not} zero. However, what are we going to do with this gigantic number? Remembering our discussion about “nice” numbers and “nice” formulae in the preceding section, let us factorise it in its prime factors.

\text{In[13]} := \texttt{FactorInteger[A[2]]}
\text{Out[13]} = \{-1, 1\}, \{2, 325\}, \{3, 39\}, \{5, 11\}, \{7, 11\}, \{11, 3\}, \{13, 2\}

I would say that this is sensational: a number with 139 digits, and the biggest prime factor is 13! As a matter of fact, this is not just a rare exception. Table 2 shows the factorisations of the first five determinants. (We could not go further because of the exploding size of the matrix of which the determinant is taken.)
\[
\begin{array}{|c|c|}
\hline
k & \det(A(k)) \\
\hline
1 & 2^{59}3^{5}7^{5}11^{3}13^{1} \\
2 & -2^{32}3^{10}5^{11}7^{11}11^{3}13^{2} \\
3 & 2^{17}1^{16}5^{28}17^{11}17^{18}17^{4}19^{3}23^{1} \\
4 & -2^{19}1^{13}3^{11}5^{11}7^{13}13^{21}17^{22}19^{23}23^{5}29^{2}31^{1} \\
5 & 2^{29}1^{32}3^{20}2^{3}5^{5}11^{29}13^{27}17^{28}19^{29}23^{9}29^{6}31^{5}37^{2} \\
\hline
\end{array}
\]

Table 2

Thus, these experimental results make us sure that there must be a “nice” formula for the determinant. Indeed, we prove in [5] that

\[
\det(A(k)) = (-1)^{k-1}2^{16k^3 + 20k^2 + 6k}k^{8k^2 + 2k}(4k + 1) \prod_{j=1}^{4k} \frac{(2j)!}{j!^2}. \tag{3.7}
\]

Hence the desired theorem follows.

**Theorem 8.** For all \( k \geq 1 \) there is a formula

\[
\pi = \sum_{n=0}^{\infty} \frac{S_k(n)}{(8k^3)!(-4)^k n},
\]

where \( S_k(n) \) is a polynomial in \( n \) of degree \( 4k \) with rational coefficients. The polynomial \( S_k(n) \) can be found by solving the previously described system of linear equations.

I must admit that we were extremely lucky that it was indeed possible to evaluate the determinant explicitly. To recall, “all” we needed to prove our theorem (Theorem 8) was to show that the determinant was non-zero. To be honest, I would not have the slightest idea how to do this here without finding the exact value of the determinant.

Now, after all this somewhat “dry” discussion, let me present the determinant. We had to determine the determinant of the \( 16k^2 \times 16k^2 \) matrix

\[
\begin{pmatrix}
0 & \cdots & 0 & \cdots & 0 & \cdots & 0 & \cdots & 0 \\
F_1 & 0 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 \\
G_1 & F_2 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 \\
0 & G_2 & F_3 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0 & 0 & G_3 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\
\vdots & \vdots & \vdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & F_{4k-1} \\
0 & 0 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & G_{4k} \\
0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{pmatrix}, \tag{3.8}
\]

\[ ^{13}\text{Strictly speaking, this is not a formula } NICE(k) \text{ according to my “Definition” in the preceding section, because of the presence of the “Abelian” factors } k^{8k^2 + 2k} \text{ and } (4k + 1)^{4k}, \text{ see Footnote 5. Nevertheless, the reader will certainly admit that this is a nice and closed formula.} \]
where the $\ell$-th non-zero entry in the first row (these are marked by * ) is
\[
(-1)^{\ell-1} (-4)^{\ell+1} k 8k(4k + 1) \left( \prod_{i=1}^{\ell-1} (4ik - 1) \right) \left( \prod_{i=1}^{\ell-1} (4ik + 1) \right),
\]
and where each block $F_t$ and $G_t$ is a $(4k-1) \times (4k)$ matrix (that is, these are rectangular blocks!) with non-zero entries only on its (two) main diagonals,
\[
F_t = \begin{pmatrix}
    f_1(4(t-1)k+1) & f_0(4(t-1)k+2) & 0 & \ldots & 0 \\
    0 & f_1(4(t-1)k+2) & f_0(4(t-1)k+3) & \ldots & 0 \\
    \vdots & \vdots & \ddots & \ddots & \vdots \\
    0 & \ldots & 0 & f_1(4tk-2) & f_0(4tk-1) \\
    f_1(4tk-2) & f_0(4tk-1) & 0 & \ldots & \ldots
\end{pmatrix}
\]
and
\[
G_t = \begin{pmatrix}
    g_1(4(t-1)k+1) & g_0(4(t-1)k+2) & 0 & \ldots & 0 \\
    0 & g_1(4(t-1)k+2) & g_0(4(t-1)k+3) & \ldots & 0 \\
    \vdots & \vdots & \ddots & \ddots & \vdots \\
    0 & \ldots & 0 & g_1(4tk-2) & g_0(4tk-1) \\
    g_1(4tk-2) & g_0(4tk-1) & 0 & \ldots & \ldots
\end{pmatrix}
\]
We have almost worked our way through the definition of the determinant. The only missing piece is the definition of the functions $f_0, f_1, g_0, g_1$ in the blocks $F_t$ and $G_t$. Here it is:
\[
    f_0(j) = j(-4)^k,
    f_1(j) = -(4j + 2)(-4)^k,
    g_0(j) = (N(k) - j),
    g_1(j) = -(4N(k) - 4j - 2)
\]
where, as before, we write $N(k) = 4k(4k + 1)$ for short.

4. The evaluation of the determinant

I now describe how the determinant of \((3.8)\) was evaluated by applying to it the methods described in [103]. To make this section as self-contained as possible, for each of them I briefly recall how it works before putting it into action.

"Method" 6: Do row and column operations until the determinant reduces to something manageable.

In fact, at a first glance, this does not look too bad. Our matrix \((3.8)\), of which we want to compute the determinant and show that it is non-zero, is a very sparse matrix. Moreover, it looks almost like a two-diagonal matrix. It seems that one should be able to do a few row and column manipulations and thus reduce the matrix to a matrix of a simpler form of which we can evaluate the determinant.

Well, we tried that. Unfortunately, the above impression is deceiving. First of all, the diagonals of the blocks do not really fit together to form diagonals which run from one end of the matrix to the other. Second, there remains still the first row which does not fit the pattern of the rest of the matrix. So, whatever we did, we ended up nowhere. Maybe we should try something more sophisticated ...
Method 1 [103, Sec. 2.6]: LU-factorisation. Suppose we are given a family of matrices $A(1), A(2), A(3), \ldots$ of which we want to compute the determinants. Suppose further that we can write

$$A(k) \cdot U(k) = L(k),$$

where $U(k)$ is an upper triangular matrix with 1s on the diagonal, and where $L(k)$ is a lower triangular matrix. Then, clearly,

$$\det(A(k)) = \text{product of the diagonal entries of } L(k).$$

But how do we find $U(k)$ and $L(k)$? We go to the computer, crank out $U(k)$ and $L(k)$ for $k = 1, 2, 3, \ldots$, until we are able to make a guess. Afterwards we prove the guess by proving the corresponding identities.

Well, we programmed that, we stared at the output on the computer screen, but we could not make any sense of it.

Method 2 [103, Sec. 2.3]: Condensation. This is based on a determinant formula due to Jacobi (see [27, Ch. 4] and [94, Sec. 3]). Let $A$ be an $n \times n$ matrix. Let $A^{i_1, i_2, \ldots, i_\ell}$ denote the submatrix of $A$ in which rows $i_1, i_2, \ldots, i_\ell$ and columns $j_1, j_2, \ldots, j_\ell$ are omitted. Then there holds

$$\det A \cdot \det A^{1, n}_n = \det A^{1}_1 \cdot \det A^{n}_n - \det A^{1}_1 \cdot \det A^{n}_n. \quad (4.1)$$

If we consider a family of matrices $A(1), A(2), \ldots$, and if all the consecutive minors of $A(n)$ belong to the same family, then this allows one to give an inductive proof of a conjectured determinant evaluation for $A(n)$.

Let me illustrate this by reproducing Amdeberhan’s condensation proof [8] of (2.11). Let $M_n(x, y)$ denote the determinant in (2.11). Then we have

$$
\begin{align*}
(M_n(x, y))^n_n &= M_{n-1}(x, y), \\
(M_n(x, y))^{1}_1 &= M_{n-1}(x + 1, y + 1), \\
(M_n(x, y))^{1}_n &= M_{n-1}(x - 1, y + 2), \\
(M_n(x, y))^{n}_1 &= M_{n-1}(x + 2, y - 1), \\
(M_n(x, y))^{1, n}_n &= M_{n-2}(x + 1, y + 1). \\
\end{align*}
\quad (4.2)
$$

Thus, we know that Equation (4.1) is satisfied with $A$ replaced by $M_n(x, y)$, where the minors appearing in (4.1) are given by (4.2). This can be interpreted as a recurrence for the sequence $(M_n(x, y))_{n \geq 0}$. Indeed, given $M_0(x, y)$ and $M_1(x, y)$, the equation (4.1) determines $M_n(x, y)$ uniquely for all $n \geq 0$ (given that $M_n(x, y)$ never vanishes). Thus, since the right-hand side of (2.11) is indeed never zero, for the proof of (2.11) it suffices to check (2.11) for $n = 0$ and $n = 1$, and that the right-hand side of (2.11) also satisfies (4.1), all of which is a routine task.

Now, a short glance at the definition of our matrix (3.8) will convince us quickly that application of this method to it is rather hopeless. For example, omission of the first row already brings us outside of our family of matrices. So, also this method is not much help to solve our problem, which is really a pity, because it is the most painless of all ...
Method 3 [103, Sec. 2.4]: Identification of factors. In order to sketch the idea, let us quickly go through a (standard) proof of the Vandermonde determinant evaluation,

\[ \det_{1 \leq i, j \leq n} (X_i^{j-1}) = \prod_{1 \leq i < j \leq n} (X_j - X_i). \tag{4.3} \]

Proof. If \( X_{i_1} = X_{i_2} \) with \( i_1 \neq i_2 \), then the Vandermonde determinant (4.3) certainly vanishes because in that case two rows of the determinant are identical. Hence, \((X_i - X_{i_1})\) divides the determinant as a polynomial in the \( X_i \)'s. But that means that the complete product \( \prod_{1 \leq i < j \leq n} (X_j - X_i) \) (which is exactly the right-hand side of (4.3)) must divide the determinant.

On the other hand, the determinant is a polynomial in the \( X_i \)'s of degree at most \( \binom{n}{2} \). Combined with the previous observation, this implies that the determinant equals the right-hand side product times, possibly, some constant. To compute the constant, compare coefficients of \( X_1^n X_2^{n-1} \cdots X_n^{n-1} \) on both sides of (4.3). This completes the proof of (4.3). \( \square \)

At this point, let us extract the essence of this proof. The basic steps are:

(S1) Identification of factors
(S2) Determination of degree bound
(S3) Computation of the multiplicative constant.

As I report in [103], this turns out to be an extremely powerful method which has numerous applications. To given an idea of the flavour of the method, I show a few steps when it is applied to the determinant in (2.11) (ignoring the fact that we have already found a very simple proof of its evaluation; see [99, proof of Theorem 10] for the complete proof using the “identification of factors” method).

To get started, we have to transform the assertion (2.11) into an assertion about polynomials. This is easily done, we just have to factor

\[ (x + y + i - 1)/(x + 2i)!/(y + 2n - i - 2)! \]

out of the \( i \)-th row of the determinant. If we subsequently cancel common factors on both sides of (2.11), we arrive at the equivalent assertion

\[
\begin{align*}
\det_{0 \leq i, j \leq n-1} ((x + y + i)_j (x + 2i - j + 1)_j (y + 2j - i + 1)_{2n-2j-2}) \\
= \prod_{i=0}^{n-1} (i! (y + 2i + 1)_n - 1 (2x + y + 2i)_i (x + 2y + 2i)_i),
\end{align*}
\]  

(4.4)

where, as before, \((\alpha)_k\) is the standard notation for shifted factorials (Pochhammer symbols) explained in the statement of Theorem 7.

In order to apply the same idea as in the above evaluation of the Vandermonde determinant, as a first step we have to show that the right-hand side of (4.4) divides the determinant on the left-hand side as a polynomial in \( x \) and \( y \). For example, we would have to prove that \((x + 2y + 2n - 2)\) (actually, \((x + 2y + 2n - 2)\) \(\lceil (n+1)/2 \rceil\), we will come to that in a moment) divides the determinant. Equivalently, if we set \( x = -2y - 2n + 2 \) in the determinant, then it should vanish. How could we prove that? Well, if it vanishes then there must be a linear combination of the columns, or of the rows, that vanishes. Equivalently, for \( x = -2y - 2n + 2 \) we find a vector in the kernel of the matrix in
(4.4), respectively of its transpose. More generally (and this addresses the fact that we actually want to prove that \((x+2y+2n-2)^{(n-1)/3}\) divides the determinant):

**For proving that \((x+2y+2n-2)^E\) divides the determinant, we find \(E\) linear independent vectors in the kernel.**

(For a formal justification that this does indeed suffice, see Section 2 of [10], and in particular the Lemma in that section.)

Okay, how is this done in practice? You go to your computer, crank out these vectors in the kernel, for \(n = 1, 2, 3, \ldots\), and try to make a guess what they are in general. To see how this works, let us do it in our example. First of all, we program the kernel of the matrix in (4.4) with \(x = -2y - 2n + 2\) (again, we are using Mathematica here).\(^{14}\)

\[
\text{In[14]:=} \quad p=\text{Pochhammer};
\]

\[
m[i_\ldots,i_\ldots,n_\ldots]:=p[x+y+i, j]*p[y+2*j+1-i, 2*n-2*j-2]*p[x-j+1+2i,j];
\]

\[
V[n_\ldots]:=(x=-2y-2n+2;
\]

\[
\text{Var} = \text{Sum}[c[j] \text{Table}[m[i,j,n],\{i,0,n-1\}],\{j,0,n-1\}];
\]

\[
\text{Var} = \text{Solve} [\text{Var} = \text{Table}[0,\{n\}],\text{Table}[c[i],\{i,0,n-1\}]]; \quad \text{Factor}[\text{Table}[c[i],\{i,0,n-1\}]/\text{Var}])
\]

What the computer gives is the following:

\[
\text{In[15]:=} \quad V[2]
\]

\[
\text{Out[15]}= \{\{-2 \ c[1], \ c[1]\}\}
\]

\[
\text{In[16]:=} \quad V[3]
\]

\[
\text{Out[16]}= \{\{-2 \ c[2], - c[2], \ c[2]\}\}
\]

\[
\text{In[17]:=} \quad V[4]
\]

\[
\text{Out[17]}= \{\{-2 \ c[3], -3 \ c[3], 0, \ c[3]\}\}
\]

\[
\text{In[18]:=} \quad V[5]
\]

\[
\text{Out[18]}= \{\{-2 \ c[4], -5 \ c[4], -2 \ c[3] - c[4], \ c[3], \ c[4]\}\}
\]

\[
\text{In[19]:=} \quad V[6]
\]

\[
\text{Out[19]}= \{\{-2 \ c[5], -7 \ c[5], -2 \ (c[4] + 2 \ c[5]), -c[4], \ c[4], \ c[5]\}\}
\]

\[
\text{In[20]:=} \quad V[7]
\]

\[
\text{Out[20]}= \{\{-2 \ c[6], -9 \ c[6], -2 \ c[5] - 9 \ c[6], -3 \ c[5] - c[6], 0,
\]

\[
\quad c[5], \ c[6]\}\}
\]

At this point, the computations become somewhat slow. So we should help our computer. Indeed, on the basis of what we have obtained so far, it is “obvious” that, somewhat unexpectedly, \(y\) does not appear in the result. Therefore we simply set \(y\) equal to some random number, and then the computer can go much further without any effort.

\[
\text{In[21]:=} \quad y=101
\]

\(^{14}\)In the program, \(V[n]\) represents the kernel, which is clearly a vector space. In the computer output, it is given in parametric form, the parameters being the \(c[i]\)'s.
Let us extract some information out of these data. For convenience, we write $M_n$ for the matrix in (4.4) in the sequel. For example, by just looking at the coefficients of $c[n - 1]$ appearing in $V[n]$, we extract that

the vector $(-2, 1)$ is in the kernel of $M_2$,
the vector $(-2, -1, 1)$ is in the kernel of $M_3$,
the vector $(-2, -3, 0, 1)$ is in the kernel of $M_4$,
the vector $(-2, -5, -1, 0, 1)$ is in the kernel of $M_5$,
the vector $(-2, -7, -4, 0, 0, 1)$ is in the kernel of $M_6$,
the vector $(-2, -9, -9, -1, 0, 0, 1)$ is in the kernel of $M_7$,
the vector $(-2, -11, -16, -5, 0, 0, 0, 1)$ is in the kernel of $M_8$,
the vector $(-2, -13, -25, -14, -1, 0, 0, 0, 1)$ is in the kernel of $M_9$,
the vector $(-2, -15, -36, -30, -6, 0, 0, 0, 0, 1)$ is in the kernel of $M_{10}$,
the vector $(-2, -17, -49, -55, -20, -1, 0, 0, 0, 0, 1)$ is in the kernel of $M_{11}$.

Okay, now we have to make sense out of this. Our vectors in the kernel have the following structure: first, there are some negative numbers, then follow a few zeroes, and finally there is a trailing 1. I believe that we do not have any problem to guess what the zeroeth\footnote{The indexing convention in the matrix in (4.4) of which the determinant is taken is that rows and columns are indexed by $0, 1, \ldots, n - 1$. We keep this convention here.} or the first coordinate of our vector is. Since the second coordinates are always negatives of squares, there is also no problem there. What about the third coordinates? Starting with the vector for $M_7$, these are $-1, -5, -14, -30, -55, \ldots$. I guess, rather than thinking hard, we should consult {\bf Rate} (see Footnote 4):
In[26]:= Rate[-1, -5, -14, -30, -55]  
   -((10 (1 + 10) (1 + 2 i 10))  
0Out[26]= {--------------------------}  
   6  

After replacing 10 by \(n - 6\) (as we should), this becomes \(-(n - 6)(n - 5)(2n - 11)/6\). An interesting feature of this formula is that it also works well for \(n = 6\) and \(n = 5\). Equipped with this experience, we let Rate work out the fourth coordinate:  
In[27]:= Rate[0, 0, 0, -1, -6, -20]  
   2  
   -((-3 + i 10) (-2 + i 10) (-1 + i 10))  
0Out[27]= {--------------------------}  
   12  

After replacement of 10 by \(n - 5\), this is \(-(n - 8)(n - 7)^2(n - 6)/12\). Let us summarise our results so far: the first five coordinates of our vector in the kernel of \(M_n\) are  
\[-2, -(2n - 5), \frac{(n - 4)(2n - 8)}{2}, \frac{(n - 6)(n - 5)(2n - 11)}{6}, \frac{(n - 8)(n - 7)(n - 6)(2n - 14)}{12}\]  
I would say, there is a clear pattern emerging: the \(s\)-th coordinate is equal to  
\[-\frac{(n - 2s)_{s-1} (2n - 3s - 2)}{s!} = \frac{(2n - 3s - 2)(n - 2s)}{(n - s - 1)s!}\]  
Denoting the above expression by \(f(n, s)\), the vector  
\((f(n, 0), f(n, 1), \ldots, f(n, n - 2), 1)\)  
is apparently in the kernel of \(M_n\) for \(n \geq 2\). To prove this, we have to show that  
\[
\sum_{s=0}^{n-2} \frac{(2n - 3s - 2)(n - 2s)_s}{(n - s - 1)(s)!} \cdot (-y - 2n + i + 2)_s (-2y - 2n + 2i - s + 3)_s (y + 2s - i + 1)_{2n-2s-2} \]
\[
= (-y - 2n + i + 2)_{n-1} (-2y - 3n + 2i + 4)_{n-1}.
\]
In [99] it was argued that this identity follows from a certain hypergeometric identity due to Singh [161]. However, for just having some proof of this identity, this careful literature search was not necessary. In fact, nowadays, once you write down a binomial or hypergeometric identity, it is already proved! One simply puts the binomial/hypergeometric sum into the Gosper–Zeilberger algorithm (see [136, 185, 186, 187]), which outputs a recurrence for it, and then the only task is to verify that the (conjectured) right-hand side also satisfies the same recurrence, and to check the identity for sufficiently many initial values (which one has already done anyway while producing the conjecture).\footnote{As you may have suspected, this is again a little bit oversimplified. But not much. The Gosper–Zeilberger algorithm applies \textit{always} to hypergeometric sums, and there are only very few \textit{binomial} sums where it does not apply. (For the sake of completeness, I mention that there are}
As I mentioned earlier, actually we need more vectors in the kernel. However, this is not difficult. Take a closer look, and you will see that the pattern persists (set \( c[n - 1] = 0 \) in the vector for \( V[n] \), etc.). It will take you no time to work out a full-fledged conjecture for \( [(n + 1)/3] \) linear independent vectors in the kernel of \( M_n \).

I do not want to go through Steps (S2) and (S3), that is, the degree calculation and the computation of the constant. As it turns out, to do this conveniently you need to introduce more variables in the determinant in (4.4). Once you do this, everything works out very smoothly. I refer the reader to [99] for these details.

Now, let us come back to our determinant, the determinant of (3.8), and apply "identification of factors" to it.\(^{17}\) To begin with, here is bad news: "identification of factors" crucially requires the existence of indeterminates. But, where are they in (3.8)? If we look at the definition of the matrix (3.8), which, in the end, depends on the auxiliary functions \( f_0, f_1, g_0, g_1 \) defined in (3.9), then we see that there are no indeterminates at all. Everything is (integral) numbers. So, to get even started, we need to introduce indeterminates in a way such that the more general determinant would still factor "nicely." We do not have much guidance. Maybe, since we already made the abbreviation \( N(k) = 4k(4k + 1) \), we should replace \( N(k) \) by \( X \)? Okay, let us try this, that is, let us put

\[
\begin{align*}
  f_0(j) &= j(-4)^k, \\
  f_1(j) &= -(4j + 2)(-4)^k, \\
  g_0(j) &= (X - j), \\
  g_1(j) &= -(4X - 4j - 2)
\end{align*}
\] (4.5)

instead of (3.9). Let us compute the new determinant for \( k = 2 \). We program the new functions \( f_0, f_1, g_0, g_1 \),
\[
\text{In}[28]:= \text{f0}[	ext{x}_*, \text{t}_*, \text{j}_*] := \text{j}*(-4)^\text{k}_*; \\
\text{f1}[	ext{x}_*, \text{t}_*, \text{j}_*] := -(2 + 4*\text{j})*(-4)^\text{k}_*; \\
\text{g0}[	ext{x}_*, \text{t}_*, \text{j}_*] := (\text{X} - \text{j}); \\
\text{g1}[	ext{x}_*, \text{t}_*, \text{j}_*] := (-4*\text{X} + 2 + 4*\text{j})
\]

we enter the new determinant for \( k = 2 \),
\[
\text{In}[29]:= \text{Factor}[	ext{Det}[\text{A}[2]]]
\]

\(^{17}\)What I describe in the sequel is, except for very few excursions that ended up in a dead end, and which are therefore omitted here, the way how the determinant evaluation was found.

---

\( a > b \) Results also several algorithms available to deal with multi-sums, see [31, 182]. These do, however, rather quickly challenge the resources of today's computers.) Maple implementations written by Doron Zeilberger are available from http://www.math.temple.edu/~zeilberg, those written by Frédéric Chyzak are available from http://algo.inria.fr/chyzak/mgfun.html, Mathematica implementations written by Peter Paule, Axel Riese, Markus Schorn, Kurt Wegschaider are available from http://www.risc.uni-linz.ac.at/research/combinat/risc/software.
and, after a waiting time of more than 15 minutes,\textsuperscript{18} we obtain
\begin{verbatim}
Out[29]= -1406399608474882323154910525986576515918369681041517636

2
> 1178376235997200840000000 (-64 + X) (-48 + X) (-40 + X) 
> 3 4 5 6 7
> (-32 + X) (-24 + X) (-16 + X) (-8 + X) X 

2
> (9653078694297600 - 916000657637376 X + 36130868757760 X
> 3 4 5 6
> - 758218948608 X + 8928558848 X - 55938432 X + 145673 X )
\end{verbatim}

Not bad. There are many factors which are linear in $X$. (This is what we were after.) However, the irreducible polynomial of degree 6 gives us some headache. (The degrees of the irreducible part of the polynomial will grow quickly with $k$.) How are we going to guess what this factor could be, and, even more daunting, even if we should be able to come up with a guess, how would we go about to prove it?

So, maybe we should modify our choice of how to introduce indeterminates into the matrix. In fact, we overlooked something: maybe, in a hidden manner, the variable $X$ is also there at other places in (3.9), that is, when $X$ is specialised to $N(k) = 4k(4k + 1)$ at these places it becomes invisible. More specifically, maybe we should insert the difference $X - 4k(4k + 1)$ in the definitions of $f_0$ and $f_1$ (which would disappear for $X = 4k(4k + 1)$). So, maybe we should try:

\begin{align*}
f_0(j) &= (4k(4k + 1) - X + j)(-4)^k, \\
f_1(j) &= -(16k(4k + 1) - 4X + 2 + 4j)(-4)^k, \\
g_0(j) &= (X - j), \\
g_1(j) &= -(4X - 4j - 2),
\end{align*}

Okay, let us modify our computer program accordingly.

\textsuperscript{18} which I use to explain why our computer needs so long to calculate this determinant of a very sparse matrix of size $16 \cdot 2^2 = 64$: isn’t it true that, nowadays, determinants of matrices with several hundreds of rows and columns can be calculated without the slightest difficulty (particularly if they are very sparse)? Well, we should not forget that this is true for determinants of matrices with \textit{numerical} entries. However, our matrix (3.8) with the modified definitions (4.5) of $f_0, f_1, g_0, g_1$ has now entries which are \textit{polynomials} in $X$. Hence, when our computer algebra program applies (internally) some elimination algorithm to compute the determinant, huge rational expressions will slowly build up and will slow down the calculations (and, at times, will make our computer crash ...). As I learn from Dave Saunders, \textit{Maple} and \textit{Mathematica} do currently in fact not use the best known algorithms for dealing with determinants of matrices with polynomial entries. (This may have to do with the fact that the developers try to optimise the algorithms for numerical determinants in the first case.) It is known how to avoid the expression swell and compute polynomial matrix determinants in time about $m n^3$, where $n$ is the dimension of the matrix and $m$ is the bit length of the determinant (roughly, in univariate case, $m$ is degree times maximum coefficient length).
In[30]:= f0[k_., t_., j_.] := (4*k*(4*k + 1) - X + j)*(-4)^k;
   f1[k_., t_., j_.] := -(4*4*k*(4*k + 1) - 4*X + 2 + 4*j)*(-4)^k;
   g0[k_., t_., j_.] := (X - j);
   g1[k_., t_., j_.] := (-4*X + 2 + 4*j)

and let us compute the new determinant for \( k = 2 \):

In[31]:= Factor[Det[A[2]]]

This makes us wait for another 15 minutes, after which we are rewarded with:

Out[31]= \(-296777975397624679901369809794412104454134763494070841 \)
   > \quad 1155365196124754770317472271790417634937439881166252558632 \)
   > \quad 616674197504000000000 (-141 + 2 X) (-139 + 2 X) (-137 + 2 X) \)
   > \quad (-135 + 2 X) (-133 + 2 X) (-131 + 2 X) (-129 + 2 X)

Excellent! There is no big irreducible polynomial anymore. Everything is linear factors in \( X \). But, wait, there is still a problem: in the end (recall Step (S2)!) we will have to compare the degrees of the determinant and of the right-hand side as polynomials in \( X \). If we expand the determinant according to its definition, then the conclusion is that the degree of the determinant is bounded above by \( 16k^2 - 1 \), which, for \( k = 2 \) is equal to 31. The right-hand side polynomial however which we computed above has degree 7. This is a big gap!

I skip some other things (ending up in dead ends ...) that we tried at this point. Altogether they pointed to the fact that, apparently, one indeterminate is not sufficient. Perhaps it is a good idea to “diversify” the variable \( X \), that is, to make two variables, \( X_1 \) and \( X_2 \), out of \( X \):

\[
\begin{align*}
f_0(j) &= (4k(4k + 1) - X_2 + j)(-4)^k, \\
f_1(j) &= -(16k(4k + 1) - 4X_1 + 2 + 4j)(-4)^k, \\
g_0(j) &= (X_2 - j), \\
g_1(j) &= -(4X_1 - 4j - 2).
\end{align*}
\]

We program this,

In[32]:= f0[k_., t_., j_., i_] := (4*k*(4*k + 1) - X[2] + j)*(-4)^k;
   f1[k_., t_., j_., i_] := -(4*4*k*(4*k + 1) - 4*X[1] + 2 + 4*j)*(-4)^k;
   g0[k_., t_., j_., i_] := (X[2] - j);
   g1[k_., t_., j_., i_] := (-4*X[1] + 2 + 4*j)

and, in order to avoid overstraining our computer, compute this time the new determinant for \( k = 1 \):

In[33]:= Factor[Det[A[1]]]

After some minutes there appears

Out[33]= \( 3242591731706757120000 \) \( (-37 + 2 X[1]) \) \( (-35 + 2 X[1]) \)

\>
\[
\begin{align*}
& \quad (-33 + 2 X[1]) \quad (1 + 2 X[1] - 2 X[2]) \quad (3 + 2 X[1] - 2 X[2])
\end{align*}
\]
on the computer screen. On the positive side: the determinant still factors completely into linear factors, something which we could not expect a priori. Moreover, the degree (in $X_1$ and $X_2$) has increased, it is now equal to 9 although we were only computing the determinant for $k = 1$. However, a gap remains, the degree should be $16k^2 - 1 = 15$ if $k = 1$.

Thus, it may be wise to introduce another genuine variable, $Y$. For example, we may think of simply homogenising the definitions of $f_0, f_1, g_0, g_1$:

$$f_0(j) = (4k(4k + 1)Y - X_2 + jY)(-4)^k,$$
$$f_1(j) = -(16k(4k + 1)Y - 4X_1 + (2 + 4j)Y)(-4)^k,$$
$$g_0(j) = (X_2 - jY),$$
$$g_1(j) = -(4X_1 - (4j + 2)Y).$$

We program this,

\begin{verbatim}
In[34]:= f0[k_, t_, j_] := (4*k*(4*k + 1)*Y - X[2] + j*Y)*(-4)^k;
f1[k_, t_, j_] := -(4*4*k*(4*k + 1)*Y - 4*X[1] + (2 + 4*j)*Y)*(-4)^k;
g0[k_, t_, j_] := (X[2] - j*Y);
g1[k_, t_, j_] := (-4*X[1] + (2 + 4*j)*Y)
\end{verbatim}

we wait for some more minutes, and we obtain

\begin{verbatim}
Out[35]= -3242591731706757120000 Y (33 Y - 2 X[1]) (35 Y - 2 X[1])
\end{verbatim}

\begin{verbatim}
3
\end{verbatim}

\begin{verbatim}
2
\end{verbatim}

\begin{verbatim}
> (5 Y + 2 X[1] - 2 X[2])
\end{verbatim}

Great! The degree in $X_1, X_2, Y$ is 15, as it should be!

At this point, one becomes greedy. The more variables we have, the easier will be the proof. We “diversify” the variables $X_1, X_2, Y$, that is, we make them $X_{1,t}, X_{2,t}, Y_t$ if they appear in the blocks $F_t$ or $G_t$, respectively, $t = 1, 2, \ldots, 4k$ (cf. (3.8) and the Mathematica code for the precise meaning of this definition):

$$f_0(j) = (4k(4k + 1)Y_t - X_{2,t} + jY_t)(-4)^k,$$
$$f_1(j) = -(16k(4k + 1)Y_t - 4X_{1,t} + (2 + 4j)Y_t)(-4)^k,$$
$$g_0(j) = (X_{2,t} - jY_t),$$
$$g_1(j) = -(4X_{1,t} - (4j + 2)Y_t).$$

Now there are so many variables so that there is no way to do the factorisation of the new determinant for $k = 1$ on the computer unless one plays tricks (which we did).\footnote{See Footnote 18 for the explanation of the complexity problem. “Playing tricks” would mean to compute the determinant for various special choices of the variables $X_{1,t}, X_{2,t}, Y_t$, and then reconstruct} But let us pretend that we are able to do it:
By staring a little bit at this result (and the one that we computed for \( k = 2 \)), we extracted that, apparently, we have

\[
\det A^X = (-1)^{k-1} 4^{2k} (4k^2 + 2k + 2) k^{2k} (4k + 1) \prod_{i=1}^{4k} (i + 1)_{4k-i+1} \\
\times \prod_{a=1}^{4k-1} \left( 2X_{1,a} - (32k^2 + 2a - 1)Y_a \right) \\
\times \prod_{1 \leq a \leq b \leq 4k-1} (2X_{2,a}Y_a - 2X_{1,a}Y_b - (2b - 2a + 1)Y_a Y_b), \quad (4.7)
\]

where \( A^X \) denotes the new general matrix given through (3.8) and (4.6), and where, as before, \((\alpha)_k\) is the standard notation for shifted factorials (Pochhammer symbols).

the general result by interpolation. This is possible because we know an a priori degree bound (namely 15) for the polynomial. However, this would become infeasible for \( k = 3 \), for example. “Playing tricks” then would mean to be content with an “almost sure” guess, the latter being based on features of the (unknown) general result that are already visible in the earlier results, and on calculations done for special values of the variables. For example, if we encounter determinants \( \det M(k) \), where the \( M(k) \)'s are some square matrices, \( k = 1, 2, \ldots \), and the results for \( k = 1, 2, \ldots, k_0 - 1 \) show that \( x - y \) must be a factor of \( \det M(k) \) to some power, then one would specialise \( y \) to some value that would make \( x - y \) distinct from any other linear factors containing \( x \), and, supposing that \( y = 17 \) is such a choice, compute \( \det M(k_0) \) with \( y = 17 \). The exact power of \( x - y \) in the unspecialised determinant \( \det M(k_0) \) can then be read off from the exponent of \( x - 17 \) in the specialised one. If it should happen that it is also infeasible to calculate \( \det M(k_0) \) with \( x \) still unspecialised, then there is still a way out. In that case, one specialises \( y \) and \( x \), in such a way that \( x - y \) would be a prime \( p \) that one expects not to occur as a prime factor in any other factor of the determinant \( \det M(k_0) \). The exact power of \( x - y \) in the unspecialised determinant \( \det M(k_0) \) can then be read off from the exponent of \( p \) in the prime factorisation of the specialised determinant. See Subsections 5.7 and 5.8, and in particular Footnote 26 for further instances where this trick was applied.
explained in the statement of Theorem 7. The special case that we need in the end to prove our Theorem 8 is \( X_{1,t} = X_{2,t} = N(k) \) and \( Y_i = 1 \).

Now we are in business. Here is the **Sketch of the proof of (4.7):**

Re (S1): For each factor of the (conjectured) result (4.7), we find a linear combination of the rows which vanishes if the factor vanishes. (In other terms: if the indeterminates in the matrix are specialised so that a particular factor vanishes, we find a vector in the kernel of the transpose of the specialised matrix.) For example, to explain the factor \( (2X_{1,1} - (32k^2 + 1)Y_1) \), we found:

If \( X_{1,1} = \frac{32k^2 + 1}{2} Y_1 \), then

\[
\frac{2(X_{2,4k-1} - (N(k) - 1)Y_{4k-1})}{(-4)^{k(4k+1)+1}(16k^2 + 1) \prod_{\ell=1}^{4k-1}(4\ell k + 1)} \cdot \text{(row 0 of } A^X) \\
+ \sum_{s=0}^{4k-2} \sum_{t=0}^{4k-2} \left( \frac{(-1)^{s(k-1)+t} \prod_{\ell=0}^{s-1} 4k - 1 + 4\ell k}{4^{sk}} \prod_{\ell=0}^{s-1} 16k^2 + 1 - 4\ell k \prod_{\ell=4k-t-1}^{4k-1} X_{2,\ell-1} - (16k^2 + \ell - 1)Y_{\ell-1} \right) \cdot \text{(row } 16k^2 - (4k - 1)s - t - 1 \text{ of } A^X) = 0, \tag{4.8}
\]

as is easy to verify. (Since the coefficients of the various rows in (4.8) are rational functions in the indeterminates \( X_{1,t}, X_{2,t}, Y_i \), they are rather easy to work out from computer data. One does not even need Rate ...)

Re (S2): The total degree in the \( X_{1,t} \)'s, \( X_{2,t} \)'s, \( Y_i \)'s of the product on the right-hand side of (4.7) is \( 16k^2 - 1 \). As we already remarked earlier, the degree of the determinant is at most \( 16k^2 - 1 \). Hence, the determinant is equal to the product times, possibly, a constant.

Re (S3): For the evaluation of the constant, we compare coefficients of

\[
X_{1,1}^{4k} X_{1,2}^{4k-1} \cdots X_{1,4k-1} X_{1,2} Y_1^{2} Y_2 \cdots Y_{4k-1}^{4k-1}.
\]

After some reflection, it turns out that the constant is equal to a determinant of the same form, that is, of the form (3.8), but with auxiliary functions

\[
\begin{align*}
f_0(j) &= (N(k) + j)(-4)^k, \\
f_1(j) &= 4(-4)^k, \\
g_0(j) &= -j, \\
g_1(j) &= -4. \tag{4.9}
\end{align*}
\]

What a set-back! It seems that we are in the same situation as at the very beginning. We started with the determinant of the matrix (3.8) with auxiliary functions (3.9), and we ended up with the same type of determinant, with auxiliary functions (4.9). There is little hope though: the functions in (4.9) are somewhat simpler as those in (3.9). Nevertheless, we have to play the same game again; that is, if we want to apply the method of identification of factors, then we have to introduce indeterminates. Skipping
the experimental part, we came up with
\[
\begin{align*}
  f_0(j) &= (Z_t + j)(-4)^k, \\
  f_1(j) &= 4(-4)^k X_t, \\
  g_0(j) &= -j, \\
  g_1(j) &= -4X_t,
\end{align*}
\]
where \( t \) has the same meaning as before in (4.6). Denoting the new matrix by \( A^Z \), computer calculations suggested that apparently
\[
\det A^Z = (-1)^k - 2^{16k^3 + 20k^2 + 1} k^{4k} (4k + 1) \prod_{a=1}^{4k-1} \left( X_a^{4k+1-a} \prod_{b=0}^{a-1} (Z_a - 4b) \right). \quad (4.10)
\]
The special case that we need is \( Z_t = N(k) \) and \( X_t = 1 \).
So, we apply again the method of identification of factors. Everything runs smoothly (except that the details of the verification of the factors are somewhat more unpleasant here). When we come finally to the point that we want to determine the constant, it turns out that the constant is equal to — no surprise anymore — the determinant of a matrix of the form (3.8) with auxiliary functions
\[
\begin{align*}
  f_0(j) &= (-4)^k, \\
  f_1(j) &= 4(-4)^k, \\
  g_0(j) &= 0, \\
  g_1(j) &= -4.
\end{align*}
\]
Now, is this good or bad news? In other words, while painfully working through the steps of “identification of factors,” will we forever continue producing new determinants of the form (3.8), which we must again handle by the same method? To give it away: this is indeed very good news. The function \( g_0(j) \) vanishes identically! It makes it possible that now Method 0 (do some row and column manipulations) works. (See [5] for the details.) We are — finally — done with the proof of (4.7), and, since the right-hand side does not vanish for \( X_{1,t} = X_{2,t} = N(k) \) and \( Y_t = 1 \), with the proof of Theorem 8! \( \square \)

5. More determinant evaluations

This section complements the list of known determinant evaluations given in Section 3 of [103]. I list here several determinant evaluations which I believe are interesting or attractive, or even both, that have appeared since [103], or that I failed to mention in [103]. I also include several conjectures and open problems, some of them old, some of them new. As in [103], each evaluation is accompanied by some remarks providing information on the context in which it arose. Again, the selection of determinant evaluations presented reflects totally my taste, which must be blamed in the case of any shortcomings. The order of presentation follows loosely the order of presentation of determinants in [103].
5.1. **More Basic Determinant Evaluations.** I begin with two determinant evaluations belonging to the category “standard determinants” (see Section 2.1 in [103]). They are among those which I missed to state in [103]. The reminder for inclusion here is the paper [9]. There, Andeberhan and Zeilberger propose an automated approach towards determinant evaluations via the condensation method (see “Method 2” in Section 4). They provide a list of examples which can be obtained in that way. As they remark at the end of the paper, all of these are special cases of Lemma 5 in [103], with the exception of three, namely Eqs. (8)–(10) in [9]. In their turn, two of them, namely (8) and (9), are special cases of the following evaluation. (For (10), see Lemma 11 below.)

**Lemma 9.** Let $P(Z)$ be a polynomial in $Z$ of degree $n - 1$ with leading coefficient $L$. Then

$$
\det_{1 \leq i, j \leq n} (P(X_i + Y_j)) = L^n \prod_{i=1}^{n} \binom{n-1}{i} \prod_{1 \leq i < j \leq n} (X_i - X_j)(Y_j - Y_i).
$$

(5.1)

This lemma is easily proved along the lines of the standard proof of the Vandermonde determinant evaluation which we recalled in Section 4 (see the proof of (4.3)) or by condensation.

A multiplicative version of Lemma 9 is the following.

**Lemma 10.** Let $P(Z) = p_{n-1}Z^{n-1} + p_{n-2}Z^{n-2} + \cdots + p_0$. Then

$$
\det_{1 \leq i, j \leq n} (P(X_iY_j)) = \prod_{i=0}^{n-1} p_i \prod_{1 \leq i < j \leq n} (X_i - X_j)(Y_j - Y_i).
$$

(5.2)

On the other hand, identity (10) from [9] can be generalised to the following Cauchy-type determinant evaluation. As all the identities from [9], it can also be proved by the condensation method.

**Lemma 11.** Let $a_0, a_1, \ldots, a_{n-1}, c_0, c_1, \ldots, c_{n-1}, b, x$ and $y$ be indeterminates. Then, for any positive integer $n$, there holds

$$
\det_{0 \leq i, j \leq n-1} \left( \frac{(x + a_i + c_j)(y + bi + c_j)}{(x + a_i + bi + c_j)} \right) = b^{n-1} (n - 1)! \left( \begin{array}{c} n \\ 2 \end{array} \right) b + (n - 1)x + y + \sum_{i=1}^{n-1} a_i + \sum_{i=0}^{n-1} c_i \\
\times \prod_{0 \leq i < j \leq n-1} (c_j - c_i) \prod_{i=1}^{n-1} (y - x - a_i) \prod_{1 \leq i < j \leq n-1} ((j - i)b - a_i + a_j) \prod_{i=1}^{n-1} \prod_{j=0}^{n-1} (x + a_i + bi + c_j).
$$

(5.3)
Speaking of Cauchy-type determinant evaluations, this brings us to a whole family of such evaluations which were instrumental in Kuperberg's recent advance \[111\] on the enumeration of (symmetry classes of) alternating sign matrices. The reason that determinants, and also Pfaffians, play an important role in this context is due to Propp's discovery (described for the first time in \[55\], Sec. 7] and exploited in \[109, 111\]) that alternating sign matrices are in bijection with configurations in the six vertex model, and due to determinant and Pfaffian formulae due to Izergin \[82\] and Kuperberg \[111\] for certain multivariable partition functions of the six vertex model under various boundary conditions. In many cases, this leads to determinants which are, or are similar to, Cauchy's evaluation of the double alternant (see \[128\], vol. III, p. 311] and (5.5) below) or Schur's Pfaffian version \[158\], pp. 226/227] of it (see (5.7) below).

Let me recall that the Pfaffian \(\text{Pf}(A)\) of a skew-symmetric \((2n) \times (2n)\) matrix \(A\) is defined by

\[
\text{Pf}(A) = \sum_{\pi} (-1)^{c(\pi)} \prod_{(i,j) \in \pi} A_{ij}, \tag{5.4}
\]

where the sum is over all perfect matchings \(\pi\) of the complete graph on \(2n\) vertices, where \(c(\pi)\) is the crossing number of \(\pi\), and where the product is over all edges \((ij)\), \(i < j\), in the matching \(\pi\) (see e.g. \[171\], Sec. 2]). What links Pfaffians so closely to determinants is (aside from similarity of definitions) the fact that the Pfaffian of a skew-symmetric matrix is, up to sign, the square root of its determinant. That is, \(\det(A) = \text{Pf}(A)^2\) for any skew-symmetric \((2n) \times (2n)\) matrix \(A\) (cf. \[171\], Prop. 2.2]). See the corresponding remarks and additional references in \[103\], Sec. 2.8.

The following three theorems present the relevant evaluations. They are Theorems 15–17 from \[111\]. All of them are proved using identification of factors (see “Method 3” in Section 4). The results in Theorem 12 contain whole sets of indeterminates, whereas the results in Theorems 13 and 14 only have two indeterminates \(p\) and \(q\), respectively three indeterminates \(p, q\) and \(r\), in them. The reader must be warned that the statements in \[111\], Theorems 15–17] are often blurred by typos.

**Theorem 12.** Let \(x_1, x_2, \ldots\) and \(y_1, y_2, \ldots\) be indeterminates. Then, for any positive integer \(n\), there hold

\[
\det_{1 \leq i, j \leq n} \left( \frac{1}{x_i + y_j} \right) = \prod_{1 \leq i < j \leq n} \frac{(x_i - x_j)(y_i - y_j)}{(x_i + y_j)}, \tag{5.5}
\]

\[
\det_{1 \leq i, j \leq n} \left( \frac{1}{x_i + y_j} - \frac{1}{1 + x_i y_j} \right) = \prod_{1 \leq i < j \leq n} (1 - x_i x_j)(1 - y_i y_j)(x_j - x_i)(y_j - y_i) \prod_{1 \leq i, j \leq n} (x_i + y_j)(1 + x_i y_j) \prod_{i=1}^{n} (1 - x_i)(1 - y_k), \tag{5.6}
\]
\[
Pf_{1\leq i,j \leq 2n} \left( \frac{x_i - x_j}{x_i + x_j} \right) = \prod_{1 \leq i < j \leq 2n} \frac{x_i - x_j}{x_i + x_j}.
\]

(5.7)

\[
Pf_{1\leq i,j \leq 2n} \left( \frac{x_i - x_j}{1 - x_ix_j} \right) = \prod_{1 \leq i < j \leq 2n} \frac{x_i - x_j}{1 - x_ix_j}.
\]

(5.8)

**Theorem 13.** Let \( p \) and \( q \) be indeterminates. Then, for any positive integer \( n \), there hold

\[
\begin{aligned}
\det_{1 \leq i,j \leq n} \left( \frac{q^{n+j-i} - q^{-n-j+i}}{p^{n+j-i} - p^{-n-j+i}} \right) &= \frac{\prod_{1 \leq i,j \leq n} (p^{j-i} - p^{-j+i}) \prod_{1 \leq i,j \leq n} (qp^{j-i} - q^{-1}p^{-j+i})}{\prod_{1 \leq i,j \leq n} (p^{n+j-i} - p^{-n-j+i})}, \\
\det_{1 \leq i,j \leq n} \left( \frac{q^{j-i} + q^{-j+i}}{p^{j-i} + p^{-j+i}} \right) &= (-1)^{(\frac{n}{2})} \frac{2^n \prod_{1 \leq i,j \leq n} (p^{j-i} - p^{-j+i}) \prod_{1 \leq i,j \leq n} (qp^{j-i} - q^{-1}p^{-j+i})}{\prod_{1 \leq i,j \leq n} (p^{j-i} + p^{-j+i})},
\end{aligned}
\]

(5.9)

\[
\begin{aligned}
\det_{1 \leq i,j \leq n} \left( \frac{q^{n+j+i} - q^{-n-j-i}}{p^{n+j+i} - p^{-n-j-i}} \right) &= \prod_{1 \leq i < j \leq 2n} (p^{j-i} - p^{-j-i}) \prod_{1 \leq i,j \leq 2n+1} (qp^{j-i} - q^{-1}p^{-j+i}) \\
&= \frac{\prod_{1 \leq i,j \leq n} (p^{n+j-i} - p^{-n-j+i}) (p^{n+j+i} - p^{-n-j+i})}{\prod_{1 \leq i,j \leq n} (p^{n+j-i} - p^{-n-j+i}) (p^{n+j+i} - p^{-n-j+i})},
\end{aligned}
\]

(5.11)

\[
\begin{aligned}
\det_{1 \leq i,j \leq n} \left( \frac{q^{i+i} + q^{-j+i}}{p^{j+i} + p^{-j+i}} \right) &= \frac{2^n \prod_{1 \leq i < j \leq n} (p^{j-i} - p^{-2(j-i)}) \prod_{1 \leq i,j \leq 2n+1} (pq^{j-i} - q^{-1}p^{-j+i})}{\prod_{1 \leq i,j \leq n} (p^{j-i} + p^{-j-i}) (p^{j+i} + p^{-j+i})}.
\end{aligned}
\]

(5.12)
Theorem 14. Let $p$, $q$, and $r$ be indeterminates. Then, for any positive integer $n$, there hold

$$
Pf_{1 \leq i, j \leq 2n} \frac{(q^{j-i} - q^{-j-i})(p^{j-i} - r^{-j-i})}{(p^{j-i} - p^{-j-i})} \prod_{1 \leq i < j \leq n} (p^{n+j-i} - p^{-(n+j-i)})
$$

$$
= \prod_{1 \leq i < j \leq 2n} (p^{j-i} - p^{-j-i}) \prod_{1 \leq i, j \leq 2n+1} (q^{j-i} - q^{-j-i})(r^{j-i} - r^{-j-i})
$$

(5.13)

$$
Pf_{1 \leq i, j \leq 2n} \frac{(p^{j+i} - p^{-j-i})(p^{j-i} - p^{-j-i})}{(p^{j+i} - p^{j-i})} \frac{(q^{j+i} - q^{-j+i})}{p^{j+i} - p^{-j+i}} \frac{(q^{j-i} - q^{-j-i})}{p^{j-i} - p^{-j-i}} \prod_{1 \leq i < j \leq 2n} (p^{j+i} - p^{-j+i})
$$

(5.14)

Subsequent to Kuperberg’s work, Okada [131] related Kuperberg’s determinants and Pfaffians to characters of classical groups, by coming up with rather complex, but still beautiful determinant enumeration identities. In particular, this allowed him to settle one more of the conjectured enumeration formulae on symmetry classes of alternating sign matrices. Generalising even further, Ishikawa, Okada, Tagawa and Zeng [79] have found more such determinant identities. Putting them into the framework of certain special representations of the symmetric group, Lascoux [114] has clarified the mechanism which gives rise to these identities.

The next six determinant lemmas are corollaries of elliptic determinant evaluations due to Rosengren and Schlosser [148]. (The latter will be addressed later in Subsection 5.11.) They partly extend the fundamental determinant lemmas in [103, Sec. 2.2]. For the statements of the lemmas, we need the notion of a norm of a polynomial $a_0 + a_1 z + \cdots + a_k z^k$, which we define to be the reciprocal of the product of its roots, or, more explicitly, as $(-1)^k a_k / a_0$.

If we specialise $p = 0$ in Lemma 67, (5.115), then we obtain a determinant identity which generalises at the same time the Vandermonde determinant evaluation, Lemma 9 and Lemma 10.

Lemma 15. Let $P_1, P_2, \ldots, P_n$ be polynomials of degree $n$ and norm $t$, given by

$$
P_j(x) = (-1)^n t a_{j,0} x^n + \sum_{k=0}^{n-1} a_{j,k} x^k.
$$
Then
\[
\det_{1 \leq i,j \leq n} (P_j(x_i)) = (1 - tx_1 \cdots x_n) \left( \prod_{1 \leq i < j \leq n} (x_j - x_i) \right) \det_{1 \leq i \leq n} (a_{i,j}). \tag{5.15}
\]

\[\square\]

Further determinant identities which generalise other Weyl denominator formulae (cf. \cite[Lemma 2]{103}) could be obtained from the special case \(p = 0\) of the other determinant evaluations in Lemma 67.

A generalisation of Lemma 6 from \cite{103} in the same spirit can be obtained by setting \(p = 0\) in Theorem 74. It is given as Corollary 5.1 in \cite{148}.

**Lemma 16.** Let \(x_1, \ldots, x_n, a_1, \ldots, a_n, \text{ and } t\) be indeterminates. For each \(j = 1, \ldots, n, \) let \(P_j\) be a polynomial of degree \(j\) and norm \(ta_1 \cdots a_j.\) Then there holds

\[
\det_{1 \leq i,j \leq n} \left( P_j(x_i) \prod_{k=j+1}^{n} (1 - a_k x_i) \right) = \frac{1 - ta_1 \cdots a_n x_1 \cdots x_n}{1 - t} \prod_{i=1}^{n} P_i(1/a_i) \prod_{1 \leq i < j \leq n} a_j(x_j - x_i). \tag{5.16}
\]

\[\square\]

We continue with a consequence of Theorem 75 (see Corollary 5.3 in \cite{148}). The special case \(P_{j-1}(x) = 1, j = 1, \ldots, n,\) is Lemma A.1 of \cite{154}, which was needed in order to obtain an \(A_n\) matrix inversion that played a crucial role in the derivation of multiple basic hypergeometric series identities. A slight generalization was given in \cite[Lemma A.1]{156}.

**Lemma 17.** Let \(x_1, \ldots, x_n\) and \(b\) be indeterminates. For each \(j = 1, \ldots, n,\) let \(P_{j-1}(x)\) be a polynomial in \(x\) of degree at most \(j - 1\) with constant term 1, and let \(Q(x) = (1 - y_1 x) \cdots (1 - y_{n+1} x).\) Then there holds

\[
Q(b) \det_{1 \leq i,j \leq n} \left( x_i^{n+1-j} P_{j-1}(x_i) - b^{n+1-j} P_{j-1}(b) \frac{Q(x_i)}{Q(b)} \right) = (1 - b x_1 \cdots x_n y_1 \cdots y_{n+1}) \prod_{i=1}^{n} (x_i - b) \prod_{1 \leq i < j \leq n} (x_i - x_j). \tag{5.17}
\]

\[\square\]

Pairing the \((i,j)\)-entry in the determinant in (5.16) with itself, but with \(x_i\) replaced by \(1/x_i,\) one can construct another determinant which evaluates in closed form. The result given below is Corollary 5.5 in \cite{148}. It is the special case \(p = 0\) of Theorem 76.

**Lemma 18.** Let \(x_1, \ldots, x_n, a_1, \ldots, a_n,\) and \(c_1, \ldots, c_{n+2}\) be indeterminates. For each \(j = 1, \ldots, n,\) let \(P_j\) be a polynomial of degree \(j\) with norm \((c_1 \cdots c_{n+2} a_{j+1} \cdots a_n)^{-1}.\)
Then there holds

\[
\begin{align*}
\det_{1 \leq i,j \leq n} & \left( x_i^{n-1} \prod_{k=1}^{n+2} (1 - c_k x_i) P_j(x_i) \prod_{k=j+1}^{n} (1 - a_k x_i) \\
& -x_i^{n+1} \prod_{k=1}^{n+2} (1 - c_k x_i^{-1}) P_j(x_i^{-1}) \prod_{k=j+1}^{n} (1 - a_k x_i^{-1}) \right) \\
& = \frac{a_1 \cdots a_n}{x_1 \cdots x_n (1 - c_1 \cdots c_{n+2} a_1 \cdots a_n)} \prod_{i=1}^{n} P_i(1/a_i) \\
& \times \prod_{1 \leq i<j \leq n+2} (1 - c_i c_j) \prod_{i=1}^{n} (1 - x_i^2) \prod_{1 \leq i<j \leq n} a_j(x_i - x_j)(1 - 1/x_i x_j). \tag{5.18}
\end{align*}
\]

\[\square\]

It is worthwhile to state the limit case \(c_{n+2} \to \infty\) of this lemma separately, in which case the norm constraint on the polynomials \(P_j\) drops out, but, in return, the degree of \(P_j\) gets lowered by one (see [148, Cor. 5.8]).

**Lemma 19.** Let \(x_1, \ldots, x_n, a_2, \ldots, a_n,\) and \(c_1, \ldots, c_{n+1}\) be indeterminates. For each \(j = 1, \ldots, n,\) let \(P_{j-1}\) be a polynomial of degree at most \(j - 1.\) Then there holds

\[
\begin{align*}
\det_{1 \leq i,j \leq n} & \left( x_i^{n-1} \prod_{k=1}^{n+1} (1 - c_k x_i) P_{j-1}(x_i) \prod_{k=j+1}^{n} (1 - a_k x_i) \\
& -x_i^n \prod_{k=1}^{n+1} (1 - c_k x_i^{-1}) P_{j-1}(x_i^{-1}) \prod_{k=j+1}^{n} (1 - a_k x_i^{-1}) \right) \\
& = \prod_{i=1}^{n} P_{j-1}(1/a_i) \prod_{1 \leq i<j \leq n+1} (1 - c_i c_j) \\
& \times \prod_{i=1}^{n} x_i^{-1}(1 - x_i^2) \prod_{1 \leq i<j \leq n} a_j(x_i - x_j)(1 - 1/x_i x_j). \tag{5.19}
\end{align*}
\]

\[\square\]

Dividing both sides of (5.19) by \(\prod_{i=2}^{n} a_i^{-1}\) and then letting \(a_i\) tend to \(\infty,\) \(i = 2, 3, \ldots, n,\) we arrive at the determinant evaluation below (see [148, Cor. 5.11]). Its special case \(P_{j-1}(x) = 1, j = 1, \ldots, n,\) is Lemma A.11 of [154], needed there in order to obtain a \(C_n\) matrix inversion, which was later applied in [155] to derive multiple \(q\)-Abel and \(q\)-Rothe summations.
Lemma 20. Let \( x_1, \ldots, x_n \), and \( c_1, \ldots, c_{n+1} \) be indeterminates. For each \( j = 1, \ldots, n \), let \( P_j^{-1} \) be a polynomial of degree at most \( j - 1 \). Then there holds

\[
\det_{1 \leq i, j \leq n} \left( x_i^{n+1} \prod_{k=1}^{n+1} (1 - c_k x_i) P_j^{-1}(x_i) - x_i^{j} \prod_{k=1}^{n+1} (1 - c_k x_i^{-1}) P_j^{-1}(x_i^{-1}) \right) \\
= \prod_{i=1}^{n} P_i^{-1}(0) \prod_{1 \leq i < j \leq n+1} (1 - c_i c_j) \prod_{i=1}^{n} x_i^{-1} (1 - x_i^2) \prod_{1 \leq i < j \leq n} (x_j - x_i) (1 - 1/x_i x_j). \tag{5.20}
\]

It is an attractive feature of this determinant identity that it contains, at the same time, the Weyl denominator formulae for the classical root systems \( B_n \), \( C_n \) and \( D_n \) as special cases (cf. [103, Lemma 2]). This is seen by setting \( P_j(x) = 1 \) for all \( j \), \( c_1 = c_2 = \cdots = c_{n-1} = 0 \), and then \( c_n = 0 \), \( c_{n+1} = -1 \) for the type \( B_n \) case, \( c_n = c_{n+1} = 0 \) for the type \( C_n \) case, and \( c_n = 1 \), \( c_{n+1} = -1 \) for the type \( D_n \) case, respectively.

A determinant which is of completely different type, but which also belongs to the category of basic determinant evaluations, is the determinant of a matrix where only two (circular) diagonals are filled with non-zero elements. It was applied with advantage in [74] to evaluate Scott-type permanents.

Lemma 21. Let \( n \) and \( r \) be positive integers, \( r \leq n \), and \( x_1, x_2, \ldots, x_n, y_1, y_2, \ldots, y_n \) be indeterminates. Then, with \( d = \gcd(r, n) \), we have

\[
\det \begin{pmatrix}
  x_1 & 0 & \cdots & 0 & y_{n-r+1} & 0 \\
  0 & x_2 & 0 & \cdots & 0 & y_{n-r+2} \\
  \vdots & \ddots & \ddots & \ddots & \ddots & \ddots \\
  0 & \cdots & 0 & y_r & 0 \\
  0 & \cdots & 0 & 0 & x_n \\
  y_1 & 0 & \cdots & 0 & 0 & x_n
\end{pmatrix}
= \prod_{i=1}^{d} \left( \prod_{j=1}^{n/d} x_i^{n/(j-1)d} - (-1)^{n/d} \prod_{j=1}^{n/d} y_i^{n/(j-1)d} \right). \tag{5.21}
\]

(I.e., in the matrix there are only nonzero entries along two diagonals, one of which is a broken diagonal.)

A further basic determinant evaluation which I missed to state in [103] is the evaluation of the determinant of a skew-circulant matrix attributed to Scott [159] in [128, p. 356]. It was in fact recently used by Fulmek in [64] to find a closed form formula for the number of non-intersecting lattice paths with equally spaced starting and end points living on a cylinder, improving on earlier results by Forrester [61] on the vicious walker model in statistical mechanics, see [64, Lemma 9].
Theorem 22. Let \( n \) be a fixed positive integer, and let \( a_0, a_1, \ldots, a_{n-1} \) be indeterminates. Then
\[
\begin{vmatrix}
    a_0 & a_1 & a_2 & \cdots & a_{n-2} & a_{n-1} \\
    -a_{n-1} & a_0 & a_1 & \cdots & a_{n-3} & a_{n-2} \\
    -a_{n-2} & -a_{n-1} & a_0 & \cdots & a_{n-4} & a_{n-3} \\
    \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
    -a_1 & -a_2 & -a_3 & \cdots & a_0 \\
\end{vmatrix}
\]
\[
= \prod_{i=0}^{n-1} (a_0 + \omega^{2i+1} a_1 + \omega^{2(2i+1)} a_2 + \cdots + \omega^{(n-1)(2i+1)} a_{n-1}),
\]
where \( \omega \) is a primitive \((2n)\)-th root of unity.

\[\square\]

5.2. More Confluent Determinants. Here I continue the discussion from the beginning of Section 3 in [103, Theorems 20–24]. There I presented determinant evaluations of matrices which, essentially, consist of several vertical strips, each of which is formed by taking a certain column vector and gluing it together with its derivative, its second derivative, etc., respectively by a similar construction where the derivative is replaced by a difference or \( q \)-difference operator.

Since most of this subsection will be under the influence of the so-called “\( q \)-disease,” we shall need the standard \( q \)-notations \( (a; q)_k \), denoting the \( q \)-shifted factorial and being given by \( (a; q)_0 := 1 \) and
\[
(a; q)_k := (1 - a)(1 - aq) \cdots (1 - aq^{k-1})
\]
if \( k \) is a positive integer, as well as \( \binom{a}{k} \), denoting the \( q \)-binomial coefficient and being defined by \( \binom{a}{0} = 1 \), and
\[
\binom{a}{k} := \frac{(1 - q^a)(1 - q^{a-1}) \cdots (1 - q^{a-k+1})}{(1 - q^a)(1 - q^{k-1}) \cdots (1 - q)}
\]
if \( k \) is a positive integer. Clearly we have \( \lim_{q \to 1} \binom{a}{k} = \binom{a}{k} \).

\[\footnote{The distinctive symptom of this disease is to invariably raise the question “Is there also a \( q \)-analogue?” My epidemiological research on MathSciNet revealed that, while basically non-existent during the 1970s, this disease slowly spread during the 1980s, and then had a sharp increase around 1990, when it jumped from about 20 papers per year published with the word “\( q \)-analogue” in it to over 80 in 1995, and since then it has been roughly stable at 60–70 papers per year. In its simplest form, somebody who is infected by this disease takes a combinatorial identity, and replaces every occurrence of a positive integer \( n \) by its “\( q \)-analogue” \( 1 + q + q^2 + \cdots + q^{n-1} \), inserts some powers of \( q \) at the appropriate places, and hopes that the result of these manipulations would be again an identity, thus constituting a “\( q \)-analogue” of the original equation. I refer the reader to the bible [66] for a rich source of \( q \)-identities, and for the right way to look at (most) combinatorial \( q \)-identities. In another form, given a certain set of objects of which one knows the exact number, one defines a statistics stat on these objects and now tries to evaluate \( \sum_{\text{O w. object}} q^{\text{stat}(O)} \). For a very instructive text following these lines see [59], with emphasis on the objects being permutations. There is also an important third form of the disease in which one works in the ring of polynomials in variables \( x, y, \ldots \) with coefficients being rational functions in \( q \), and in which some pairs of variables satisfy commutation relations of the type \( xy = qyx \). The study of such polynomial rings and algebras is often motivated by quantum groups and quantum algebras. The reader may want to consult [98] to learn more about this direction. While my description did not make this clear, the three described forms of the \( q \)-disease are indeed strongly inter-related.}
The first result that I present is a $q$-extension of the evaluation of the confluent alternant due to Schmied [153] (cf. [153, paragraph before Theorem 20]). In fact, Theorem 23 of [103] already provided a $q$-extension of (a generalisation of) Schmied’s formula. However, in [87, Theorem 1], Johnson found a different $q$-extension. The theorem below is a slight generalisation of it. (The theorem below reduces to Johnson’s theorem if one puts $C = 0$. For $q = 1$, the theorem below and [103, Theorem 23] become equivalent. To go from one determinant to the other in this special case, one would have to take a certain factor out of each column.)

**Theorem 23.** Let $n$ be a non-negative integer, and let $A_m(X)$ denote the $n \times m$ matrix

$$
\left( \begin{bmatrix} C + i \\ i - j \end{bmatrix} (X; q)_{i-j} \right)_{0 \leq i \leq n-1, 0 \leq j \leq m-1}.
$$

Given a composition of $n$, $n = m_1 + \cdots + m_{\ell}$, there holds

$$
\det_{n \times n} \left( A_{m_1}(X_1) A_{m_2}(X_2) \cdots A_{m_{\ell}}(X_{\ell}) \right) = q^{\sum_{1 \leq i < j \leq \ell} m_i m_j m_k} \prod_{1 \leq i < j \leq \ell} \prod_{g=1}^{m_i} \prod_{h=1}^{m_j} \left( q^{h-1} X_i - q^{g-1} X_j \right) \left( 1 - q^{C+g+h-1+\sum_{i=1}^{\ell} m_i} \right) \left( 1 - q^{g+h-1+\sum_{i=1}^{\ell} m_i} \right) .
$$

(5.23)

\[ \square \]

In [87, Theorem 2], Johnson provides as well a confluent $q$-extension of the evaluation of Cauchy’s double alternant (5.5). Already the case $q = 1$ seems to not have appeared in the literature earlier. Here, I was not able to introduce an additional parameter (as, for example, the $C$ in Theorem 23).

**Theorem 24.** Let $n$ be a non-negative integer, and let $A_m(X)$ denote the $n \times m$ matrix

$$
\left( \frac{1}{(Y_i - X)(Y_i - qX)(Y_i - q^2X) \cdots (Y_i - q^{l-1}X)} \right)_{1 \leq i \leq n, 1 \leq j \leq m}.
$$

Given a composition of $n$, $n = m_1 + \cdots + m_{\ell}$, there holds

$$
\det_{n \times n} \left( A_{m_1}(X_1) A_{m_2}(X_2) \cdots A_{m_{\ell}}(X_{\ell}) \right) = \frac{\prod_{1 \leq i < j \leq n} (Y_i - Y_j)}{n} \prod_{1 \leq i < j \leq \ell} \prod_{g=1}^{m_i} \prod_{h=1}^{m_j} \left( q^{h-1} X_i - q^{g-1} X_j \right) .
$$

(5.24)

\[ \square \]

A surprising mixture between the confluent alternant and a confluent double alternant appears in [36, Theorem A.1]. Ciucu used it there in order to prove a Coulomb gas law and a superposition principle for the joint correlation of certain collections of holes for the rhombus tiling model on the triangular lattice. (His main result is in fact based on an even more general, and more complex, determinant evaluation, see [36, Theorem 8.1].)
Theorem 25. Let $s_1, s_2, \ldots, s_m \geq 1$ and $t_1, t_2, \ldots, t_n \geq 1$ be integers. Write $S = \sum_{i=1}^m s_i$, $T = \sum_{j=1}^n t_j$, and assume $S \geq T$. Let $x_1, x_2, \ldots, x_m$ and $y_1, y_2, \ldots, y_n$ be indeterminates. Define $N$ to be the $S \times S$ matrix

$$N = \begin{bmatrix} A & B \end{bmatrix}$$

whose blocks are given by

$$A = \begin{bmatrix} \frac{\binom{s}{0}}{y_1 - x_1} & \frac{\binom{1}{0}}{y_1 - x_1} & \cdots & \frac{\binom{s-1}{0}}{y_1 - x_1} & \frac{\binom{s}{1}}{y_1 - x_1} & \cdots & \frac{\binom{s-1}{1}}{y_1 - x_1} \\ \frac{\binom{s}{0}}{y_1 - x_2} & \frac{\binom{1}{0}}{y_1 - x_2} & \cdots & \frac{\binom{s-1}{0}}{y_1 - x_2} & \frac{\binom{s}{1}}{y_1 - x_2} & \cdots & \frac{\binom{s-1}{1}}{y_1 - x_2} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \frac{\binom{s}{0}}{y_1 - x_m} & \frac{\binom{1}{0}}{y_1 - x_m} & \cdots & \frac{\binom{s-1}{0}}{y_1 - x_m} & \frac{\binom{s}{1}}{y_1 - x_m} & \cdots & \frac{\binom{s-1}{1}}{y_1 - x_m} \\ \end{bmatrix}$$

and

$$B = \begin{bmatrix} \binom{0}{0} x_1^0 & \binom{0}{1} x_1^1 & \cdots & \binom{0}{s-1} x_1^{s-1} & \frac{1}{1-x_1} x_1^0 & \cdots & \frac{1}{1-x_1} x_1^{s-1} \\ \frac{0}{1} x_1^0 & \binom{1}{0} x_1^1 & \cdots & \binom{1}{s-1} x_1^{s-1} & \frac{1}{1-x_1} x_1^0 & \cdots & \frac{1}{1-x_1} x_1^{s-1} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \frac{0}{s-1} x_1^0 & \binom{s-1}{0} x_1^1 & \cdots & \binom{s-1}{s-1} x_1^{s-1} & \frac{1}{1-x_1} x_1^0 & \cdots & \frac{1}{1-x_1} x_1^{s-1} \\ \end{bmatrix}$$

Then we have

$$\det N = \frac{\prod_{1 \leq i < j \leq m} (x_j - x_i)^{s_{i,j}} \prod_{1 \leq i < j \leq n} (y_j - y_i)^{t_{i,j}}}{\prod_{i=1}^m \prod_{j=1}^n (y_j - x_i)^{s_{i,j}}}.$$
This theorem generalises at the same time numerous previously obtained determinant evaluations. It reduces of course to Cauchy’s double alternant when \( m = n \) and \( s_1 = s_2 = \cdots = s_m = t_1 = t_2 = \cdots = t_n = 1 \). (In that case, the submatrix \( B \) is empty.) It reduces to the confluent alternant for \( t_1 = t_2 = \cdots = t_n = 0 \) (i.e., in the case where the submatrix \( A \) is empty). The case \( m = r n \), \( s_1 = s_2 = \cdots = s_m = 1, t_1 = t_2 = \cdots = t_n = r \) is stated as an exercise in [129, Ex. 42, p. 360]. Finally, a mixture of the double alternant and the Vandermonde determinant appeared already in [74, Theorem (Cauchy+)] where it was used to evaluate Scott-type permanents. This mixture turns out to be the special case \( s_1 = s_2 = \cdots = s_m = t_1 = t_2 = \cdots = t_n = 1 \) (but not necessarily \( m = n \)) of Theorem 25.

If \( S = T \) (i.e., in the case where the submatrix \( B \) is empty), Theorem 25 provides the evaluation of a confluent double alternant which is different from the one in Theorem 24 for \( C = 0 \) and \( q = 1 \). While, for the general form of Theorem 25, I was not able to find a \( q \)-analogue, I was able to find one for this special case, that is, for the case where \( B \) is empty. In view of the fact that there are also \( q \)-analogues for the other extreme case where the submatrix \( A \) is empty (namely Theorem 23 and [103, Theorem 23]), I still suspect that a \( q \)-analogue of the general form of Theorem 25 should exist.

**Theorem 26.** Let \( s_1, s_2, \ldots, s_m \geq 1 \) and \( t_1, t_2, \ldots, t_n \geq 1 \) be integers such that \( s_1 + s_2 + \cdots + s_m = t_1 + t_2 + \cdots + t_n \). Let \( x_1, x_2, \ldots, x_m \) and \( y_1, y_2, \ldots, y_n \) be indeterminates. Let \( A \) be the matrix

\[
A = \left[ \begin{array}{cccccccc}
0 & [1]_q & \cdots & [t_1-1]_q & 0 & [1]_q & \cdots & [t_n-1]_q \\
\vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
[s_1-1]_q & s_1 & \cdots & s_1+t_1-2 & s_1-1 & s_1 & \cdots & s_1+t_n-2 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
[0]_q & [1]_q & \cdots & [t_1-1]_q & 0 & [1]_q & \cdots & [t_n-1]_q \\
\vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
[s_m-1]_q & s_m & \cdots & s_m+t_m-2 & s_m-1 & s_m & \cdots & s_m+t_n-2
\end{array} \right], \quad (5.29)
\]

where \( (x, y)^c := (y - x)(qy - x)(q^2 y - x) \cdots (q^{c-1}y - x) \). Then we have
\[
\det A = q^2 \sum_{i=1}^m (s_i - 1) s_i (2s_i - 1) \left( \prod_{1 \leq i < j \leq m} \prod_{h=1}^{s_j} (q^{s_i x_j} - q^{s_i x_i}) \right)
\times \left( \prod_{1 \leq i < j \leq n} \prod_{h=1}^{s_j} (q^{s_i y_j} - q^{s_i y_i}) \right) \frac{1}{\prod_{j=1}^{m} \prod_{i=1}^{n} \prod_{h=1}^{s_j} (q^{s_i y_j} - q^{s_i y_i})}.
\] (5.30)

5.3. More determinants containing derivatives and compositions of series. Inspired by formulae of Mina [127], Kedlaya [93] and Strehl and Wilf [172] for determinants of matrices the entries of which being given by (coefficients of) multiple derivatives and compositions of formal power series (see also [103, Lemma 16]), Chu embedded all these in a larger context in the remarkable systematic study [30]. He shows that, at the heart of these formulae, there is the Faà di Bruno formula\(^{21}\) for multiple derivatives of a composition of two formal power series. Using it, he derives the following determinant reduction formulae [30, Theorems 4.1 and 4.2] for determinants of matrices containing multiple derivatives of compositions of formal power series.

**Theorem 27.** Let \( f(x) \) and \( \phi_k(x) \) and \( w_k(x) \), \( k = 0, 1, \ldots, n \), be formal power series in \( x \) with coefficients in a commutative ring. Then

\[
\det_{0 \leq i, j \leq n} \left( \frac{d^j}{dx^j} \left( w_j(x) \phi_i(f(x)) \right) \right) = (f'(x))^{(n+1)} \left( \prod_{k=0}^n w_k(x) \right) \det_{0 \leq i, j \leq n} \left( \phi_i^{(j)}(f(x)) \right),
\] (5.31)

where \( \phi_i^{(j)}(x) \) is short for \( \frac{d^j}{dx^j} \phi_i(x) \). If, in addition, \( w_k(x) \) is a polynomial of degree at most \( k \), \( k = 1, 2, \ldots, n \), then

\[
\det_{1 \leq i, j \leq n} \left( \frac{d^j}{dx^j} \left( w_j(x) \phi_i(f(x)) \right) \right) = (f'(x))^{(n+1)} \left( \prod_{k=1}^n w_k(x) \right) \det_{1 \leq i, j \leq n} \left( \phi_i^{(j)}(f(x)) \right).
\] (5.32)

Specialising the series \( \phi_i(x) \) so that the determinants on the right-hand sides of (5.31) or (5.32) can be evaluated, he obtains numerous nice corollaries. Possible choices are \( \phi_i(x) = \exp(y_i x) \), \( \phi_i(x) = \log(1 + y_i x) \), \( \phi_i(x) = x^{y_i} \), or \( \phi_i(x) = (a_i + b_i x)/(c_i + d_i x) \). See [30, Cor. 4.3 and 4.4] for the corresponding results.

\(^{21}\)As one can read in [86], “Faà di Bruno was neither the first to state the formula that bears his name nor the first to prove it.” In Section 4 of that article, the author tries to trace back the roots of the formula. It is apparently impossible to find the author of the formula with certainty. In his book [15, p. 312], Arboagast describes a recursive rule how, from the top term, to generate all other terms in the formula. However, the explicit formula is never written down. (I am not able to verify the conclusions in [45]. It seems to me that the author mixes the knowledge that we have today with what is really written in [15].) The formula appears explicitly in Lacroix’s book [112, p. 629], but Lacroix’s precise sources remain unknown. I refer the reader to [86, Sec. 4] and [45] for more detailed remarks on the history of the formula.
series. In order to have a convenient notation, let us write \( f^{(n)}(x) \) for the \( n \)-fold composition of \( f \) with itself,

\[
f^{(n)}(x) = f(f(\cdots(f(x)))))
\]

with \( n \) occurrences of \( f \) on the right-hand side. Chu shows [30, Sec. 1.4] that it is possible to extend this \( n \)-fold composition to values of \( n \) other than non-negative integers. This given, Theorems 4.6 and 4.7 from [30] read as follows.

**Theorem 28.** Let \( f(x) = x + \sum_{m=2}^{\infty} f_m x^m \), \( g(x) = \sum_{m=1}^{\infty} g_m x^m \) and \( w_k(x) \), \( k = 1, 2, \ldots, n \), be formal power series with coefficients in some commutative ring. Then

\[
\det_{1 \leq i, j \leq n} \left( [x^j] w_j(x) f^{(y_i)}(g(x)) \right) = f_2^{(n)} g_1^{(n+1)} \left( \prod_{k=1}^{n} w_k(0) \right) \left( \prod_{1 \leq i < j \leq n} (y_j - y_k) \right),
\]

(5.33)

where \([x^j]h(x)\) denotes the coefficient of \( x^j \) in the series \( h(x) \). If, in addition, \( w_n(0) = 0 \), then

\[
\det_{1 \leq i, j \leq n} \left( [x^{j+1}] w_j(x) f^{(y_i)}(g(x)) \right) = f_2^{(n)} g_1^{(n+1)} \left( \prod_{1 \leq i < j \leq n} (y_j - y_k) \right) \det_{1 \leq i, j \leq n} \left( [x^{j-i+1}] w_j(x) \right).
\]

(5.34)

Furthermore, we have

\[
\det_{1 \leq i, j \leq n} \left( [x^{j+1}] f^{(y_i)}(x) \right) = f_2^{(n+1)} \left( \prod_{k=1}^{n} y_k \right) \left( \prod_{1 \leq i < j \leq n} (y_j - y_k) \right).
\]

(5.35)

\[\square\]

### 5.4. More on Hankel Determinant Evaluations.

Section 2.7 of [103] was devoted to **Hankel determinants**. There, I tried to convince the reader that, whenever you think that a certain Hankel determinant evaluates nicely, then the explanation will be (sometimes more sometimes less) hidden in the theory of **continued fractions** and **orthogonal polynomials**. In retrospect, it seems that the success of this try was mixed. Since readers are always right, this has to be blamed entirely on myself, and, indeed, the purpose of the present subsection is to rectify some shortcomings from then.

Roughly speaking, I explained in [103] that, given a Hankel determinant

\[
\det_{0 \leq i, j \leq n-1}(\mu_{i+j}),
\]

(5.36)
to find its evaluation one should expand the generating function of the sequence of coefficients \((\mu_k)_{k \geq 0}\) in terms of a continued fraction, respectively find the sequence of orthogonal polynomials \((p_n(x))_{n \geq 0}\) with moments \(\mu_k\), \(k = 0, 1, \ldots\), and then the value of the Hankel determinant (5.36) can be read off the coefficients of the continued fraction, respectively from the recursion coefficients of the orthogonal polynomials. What I missed to state is that the knowledge of the orthogonal polynomials makes it also possible to find the value of the Hankel determinants which start with \(\mu_1\) and \(\mu_2\), respectively (instead of \(\mu_0\)). In the theorem below I summarise the results that were already discussed in [103] (for which classical references are [178, Theorem 51.1] or [177, Cor. 6, (19)], on p. IV-17; Proposition 1, (7), on p. V-5)), and I add the two missing ones.
Theorem 29. Let \((\mu_k)_{k \geq 0}\) be a sequence with generating function \(\sum_{k=0}^{\infty} \mu_k x^k\) written in the form
\[
\sum_{k=0}^{\infty} \mu_k x^k = \frac{\mu_0}{1 + a_0 x - \frac{b_1 x^2}{1 + a_1 x - \frac{b_2 x^2}{1 + a_2 x - \cdots}}}.
\] (5.37)

Then
\[
\det_{0 \leq i, j \leq n-1} (\mu_{i+j}) = \mu_0^n b_1^{n-1} b_2^{n-2} \cdots b_{n-2}^2 b_{n-1}. \] (5.38)

Let \((p_n(x))_{n \geq 0}\) be a sequence of monic polynomials, the polynomial \(p_n(x)\) having degree \(n\), which is orthogonal with respect to some functional \(L\), that is, \(L(p_m(x)p_n(x)) = \delta_{m,n} c_n\), where the \(c_n\)'s are some non-zero constants and \(\delta_{m,n}\) is the Kronecker delta. Let
\[
p_{n+1}(x) = (a_n + x)p_n(x) - b_n p_{n-1}(x)
\] (5.39)
be the corresponding three-term recurrence which is guaranteed by Favard’s theorem.

Then the generating function \(\sum_{k=0}^{\infty} \mu_k x^k\) for the moments \(\mu_k = L(x^k)\) satisfies (5.37) with the \(a_i\)'s and \(b_i\)'s being the coefficients in the three-term recurrence (5.39). In particular, the Hankel determinant evaluation (5.38) holds, with the \(b_i\)'s from the three-term recurrence (5.39).

If \((q_n)_{n \geq 0}\) is the sequence recursively defined by \(q_0 = 1\), \(q_1 = -a_0\), and
\[
q_{n+1} = -a_n q_n - b_n q_{n-1},
\]
then in the situation above we also have
\[
\det_{0 \leq i, j \leq n-1} (\mu_{i+j+1}) = \mu_0^n b_1^{n-1} b_2^{n-2} \cdots b_{n-2}^2 b_{n-1} q_n
\] (5.40)
and
\[
\det_{0 \leq i, j \leq n-1} (\mu_{i+j+2}) = \mu_0^n b_1^{n-1} b_2^{n-2} \cdots b_{n-2}^2 b_{n-1} \sum_{k=0}^{n} q_k^2 b_{k+1} \cdots b_{n-k} b_n. \] (5.41)

\(\square\)

I did not find a reference for (5.40) and (5.41). These two identities follow however easily fromViennot’s combinatorial model [177] for orthogonal polynomials and Hankel determinants of moments. More precisely, in this theory the moments \(\mu_k\) are certain generating functions for Motzkin paths, and, due to Theorem 6, the Hankel determinants \(\det_{0 \leq i, j \leq n-1} (\mu_{i+j+m})\) are generating functions for families \((P_1, P_2, \ldots, P_n)\) of non-intersecting Motzkin paths, \(P_i\) running from \((-i,0)\) to \((j+m,0)\). In the case \(m = 0\), it is explained in [177, Ch. IV] how to find the corresponding Hankel determinant evaluation (5.38) using this combinatorial model. The idea is that in that case there is a unique family of non-intersecting Motzkin paths, and its weight gives the right-hand side of (5.38). If \(m = 1\) or \(m = 2\) one can argue similarly. The paths are uniquely determined with the exception of their portions in the strip \(0 \leq x \leq m\). The various possibilities that one has there then yield the right-hand sides of (5.40) and (5.41).

Since there are so many explicit families of orthogonal polynomials, and, hence, so many ways to apply the above theorem, I listed only a few standard Hankel determinant evaluations explicitly in [103]. I did append a long list of references and sketched in
which ways these give rise to more Hankel determinant evaluations. Apparently, these remarks were at times too cryptic, in particular concerning the theme “orthogonal polynomials as moments.” This is treated systematically in the two papers [80, 81] by Ismail and Stanton. There it is shown that certain classical polynomials \((r_n(x))_{n \geq 0}\), such as, for example, the Laguerre polynomials, the Meixner polynomials, or the Al-Salam-Chihara polynomials (but there are others as well, see [80, 81]), are moments of other families of classical orthogonal polynomials. Thus, application of Theorem 29 with \(\mu_n = r_n(x)\) immediately tells that the evaluations of the corresponding Hankel determinants

\[
\det_{0 \leq i, j \leq n-1} (r_{i+j}(x))
\]

(and also the higher ones in (5.40) and (5.41)) are known. In particular, the explicit forms can be extracted from the coefficients of the three-term recursions for these other families of orthogonal polynomials. Thus, whenever you encounter a determinant of the form (5.42), you must check whether \((r_n(x))_{n \geq 0}\) is a family of orthogonal polynomials (which, as I explained in [103], one does by consulting the compendium [96] of hypergeometric orthogonal polynomials compiled by Koekoek and Swarttouw), and if the answer is “yes”, you will find the solution of your determinant evaluation through the results in [80, 81] by applying Theorem 29.

While Theorem 29 describes in detail the connexion between Hankel determinants and the continued fractions of the type (5.37), which are often called \(J\)-fractions (which is short for Jacobi continued fractions), I missed to tell in [103] that there is also a close relation between Hankel determinants and so-called \(S\)-fractions (which is short for Stieltjes continued fractions). I try to remedy this by the theorem below (cf. for example [88, Theorem 7.2], where \(S\)-fractions are called regular \(C\)-fractions). In principle, since \(S\)-fractions are special cases of \(J\)-fractions (5.37) in which the coefficients \(a_i\) are all zero, the corresponding result for the Hankel determinants is in fact implied by Theorem 29. Nevertheless, it is useful to state it separately. I am not able to give a reference for (5.46), but, again, it is not too difficult to derive it from Viennot’s combinatorial model [177] for orthogonal polynomials and moments that was mentioned above.

**Theorem 30.** Let \((\mu_k)_{k \geq 0}\) be a sequence with generating function \(\sum_{k=0}^{\infty} \mu_k x^k\) written in the form

\[
\sum_{k=0}^{\infty} \mu_k x^k = \frac{\mu_0}{1 + \frac{a_1 x}{1 + \frac{a_2 x}{1 + \ldots}}}.
\]

Then

\[
\det_{0 \leq i, j \leq n-1} (\mu_{i+j}) = \mu_0^n (a_1 a_2)^{n-1} (a_2 a_4)^{n-2} \cdots (a_{2n-3} a_{2n-1})^2 (a_{2n-3} a_{2n-2}),
\]

\[
\det_{0 \leq i, j \leq n-1} (\mu_{i+j+1}) = (-1)^n \mu_0 a_1^n (a_2 a_3)^{n-1} (a_4 a_5)^{n-2} \cdots (a_{2n-4} a_{2n-3})^2 (a_{2n-2} a_{2n-1}),
\]

and
\[
\det_{0 \leq i,j \leq n-1} (\mu_{i+j+2}) = \mu_0 a_i^n (a_2 a_3)^{n-1} (a_4 a_5)^{n-2} \cdots (a_{2n-4} a_{2n-3})^2 \left( a_{2n-2} a_{2n-1} \right)
\times \sum_{0 \leq i_1 < i_2 < \cdots < i_n \leq n} a_{i_1} a_{i_2} \cdots a_{i_n}.
\] (5.46)

Using this theorem, Tamm [173, Theorem 3.1] observed that from Gauß' continued fraction for the ratio of two contiguous \(2F_1\)-series one can deduce several interesting binomial Hankel determinant evaluations, some of them had already been found earlier by Egcioglu, Redmond and Ryavec [50, Theorem 4] while working on polynomial Riemann hypotheses. Gessel and Xin [69] undertook a systematic analysis of this approach, and they arrived at a set of 18 Hankel determinant evaluations, which I list as (5.48)–(5.65) in the theorem below. They are preceded by the Hankel determinant evaluation (5.47), which appears only in [50, Theorem 4].

**Theorem 31.** For any positive integer \(n\), there hold

\[
\det_{0 \leq i,j \leq n-1} \left( \binom{3i + 3j + 2}{i+j} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.47)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{1}{3i + 3j + 1} \binom{3i + 3j + 1}{i+j} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.48)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{1}{3i + 3j + 1} \binom{3i + 3j + 1}{i+j+1} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.49)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{1}{3i + 3j + 2} \binom{3i + 3j + 2}{i+j+1} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.50)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{1}{3i + 3j + 2} \binom{3i + 3j + 2}{i+j+2} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.51)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{2}{3i + 3j + 3} \binom{3i + 3j + 3}{i+j+1} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.52)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{2}{3i + 3j + 3} \binom{3i + 3j + 3}{i+j+2} \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.53)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{2}{(3i + 3j + 1)(3i + 3j + 2)} \binom{3i + 3j + 2}{i+j+1} \right) = \prod_{i=0}^{n-1} 2 \left( \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \right)^2 \frac{27}{4}^i,
\] (5.54)

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{2}{(3i + 3j + 4)(3i + 3j + 5)} \binom{3i + 3j + 4}{i+j+2} \right) = (-1)^n \prod_{i=1}^{n} \frac{\left( \frac{3}{2} \right)_i \left( \frac{5}{2} \right)_i \left( \frac{7}{2} \right)_i}{\left( \frac{1}{2} \right)_{2i} \left( \frac{3}{2} \right)_{2i}} \frac{27}{4}^i,
\] (5.55)
\[
\begin{align*}
\det_{0 \leq i,j \leq n-1} & \left( \frac{(9i + 9j + 5)}{(3i + 3j + 1)(3i + 3j + 2)} \left( \frac{3i + 3j + 2}{i + j + 1} \right) \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}, \\
\det_{0 \leq i,j \leq n-1} & \left( \frac{(9i + 9j + 14)}{(3i + 3j + 4)(3i + 3j + 5)} \left( \frac{3i + 3j + 5}{i + j + 2} \right) \right) = \prod_{i=1}^{n} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\end{align*}
\]

Let \( a_0 = -2 \) and \( a_m = \frac{1}{3m+1} \binom{3m+1}{m} \) for \( m \geq 1 \). Then

\[
\det_{0 \leq i,j \leq n-1} (a_{i+j}) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Let \( b_0 = 10 \) and \( b_m = \frac{2}{3m+2} \binom{3m+2}{m} \) for \( m \geq 1 \). Then

\[
\det_{0 \leq i,j \leq n-1} (b_{i+j}) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Furthermore,

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{2}{3i + 3j + 5} \left( \frac{3i + 3j + 5}{i + j + 1} \right) \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Let \( c_0 = \frac{7}{2} \) and \( c_m = \frac{2}{3m+1} \binom{3m+1}{m+1} \) for \( m \geq 1 \). Then

\[
\det_{0 \leq i,j \leq n-1} (c_{i+j}) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Let \( d_0 = -5 \) and \( d_m = \frac{8}{3m+1} \binom{3m+1}{m} \binom{3m+2}{m+1} \) for \( m \geq 1 \). Then

\[
\det_{0 \leq i,j \leq n-1} (d_{i+j}) = \prod_{i=0}^{n-1} \left( -5 \right) \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Furthermore,

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{8}{3i + 3j + 4} \left( \frac{3i + 3j + 5}{i + j + 1} \right) \right) = \prod_{i=0}^{n-1} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Let \( e_0 = 14 \) and \( e_m = \frac{2}{3m+1} \binom{3m+1}{m} \binom{3m+2}{m} \) for \( m \geq 1 \). Then

\[
\det_{0 \leq i,j \leq n-1} (e_{i+j}) = \prod_{i=0}^{n-1} \left( 14 \right) \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]

Furthermore,

\[
\det_{0 \leq i,j \leq n-1} \left( \frac{2(9i + 9j + 14)}{(3i + 3j + 4)(3i + 3j + 5)} \left( \frac{3i + 3j + 5}{i + j + 1} \right) \right) = \prod_{i=1}^{n} \left( \frac{\left( \frac{5}{2} \right)_i}{\left( \frac{3}{2} \right)_{2i}} \right) \frac{(27/4)^{2i}}{\big( \frac{5}{2} \big)^{2i}}.
\]
Some of the numbers appearing on the right-hand sides of the formulae in this theorem have combinatorial significance, although no intrinsic explanation is known why this is the case. More precisely, the numbers on the right-hand sides of (5.48), (5.51) and (5.52) count **cyclically symmetric transpose-complementary plane partitions** (cf. [124] and [27]), whereas those on the right-hand sides of (5.47), (5.49), (5.50) and (5.53) count **vertically symmetric alternating sign matrices** (cf. [111] and [27]).

In [50, Theorem 4], Eğecioğlu, Redmond and Ryavec prove also the following common generalisation of (5.49) and (5.50). (The first identity is the special case \( x = 0 \), while the second is the special case \( x = 1 \) of the following theorem.)

**Theorem 32.** For \( m \geq 0 \), let \( s_m(x) = \sum_{k=0}^{m} \frac{k+1}{m+1} \binom{3m-k+1}{m-k} x^k \). Then, for any positive integer \( n \), there holds

\[
\det_{0 \leq i,j \leq n-1} (s_{i+j}(x)) = \prod_{i=0}^{n-1} \left( \frac{\binom{3}{2} \frac{3}{2} \frac{7}{2}}{2i} \right)^{2i} \left( \frac{27}{4} \right)^{2i}.
\]  

(5.66)

\[ \square \]

As I mentioned above, in [103] I only stated a few special Hankel determinant evaluations explicitly, because there are too many ways to apply Theorems 29 and 30. I realise, however, that I should have stated the evaluation of the **Hankel determinant of Catalan numbers** there. I make this up now by doing this in the theorem below. I did not do it then because orthogonal polynomials are not needed for its evaluation (the orthogonal polynomials which are tied to Catalan numbers as moments are **Chebyshev polynomials**, but, via Theorems 29 and 30, one would only cover the cases \( m = 0, 1, 2 \) in the theorem below). In fact, the Catalan number \( C_n = \frac{1}{n+1} \binom{2n}{n} \) can be alternatively written as \( C_n = (-1)^n 2^{2n+1} \binom{1/2}{n+1} \), and therefore the Hankel determinant evaluation below follows from [103, Theorem 26, (3.12)]. This latter observation shows that even a more general determinant, namely \( \det_{0 \leq i,j \leq n-1} (C_{i+j}) \), can be evaluated in closed form. For historical remarks on this ubiquitous determinant see [70, paragraph before the Appendix].

**Theorem 33.**

\[
\det_{0 \leq i,j \leq n-1} (C_{i+j}) = \prod_{1 \leq i \leq j \leq m-1} \frac{2n + i + j}{i + j}.
\]  

(5.67)

\[ \square \]

As in [103], let me conclude the part on Hankel determinants by pointing the reader to further papers containing interesting results on them, high-lighting sometimes the point of view of orthogonal polynomials that I explained above, sometimes a combinatorial point of view. The first point of view is put forward in [183] (see [104] for the solution of the conjectures in that paper) in order to present Hankel determinant evaluations of matrices with **hypergeometric \( _2F_1 \)-series** as entries. The orthogonal polynomials approach is also used in [46] to show that a certain Hankel determinant defined by **Catalan numbers** evaluates to **Fibonacci numbers**. In [14], one finds Hankel determinant evaluations involving generalisations of the **Bernoulli numbers**. The combinatorial point of view dominates in [4, 32, 33, 34, 51], where Hankel determinants involving **q-Catalan numbers**, **q-Stirling numbers**, and **q-Fibonacci numbers** are considered.
A very interesting new direction, which seems to have much potential, is opened up by Luque and Thibon in [119]. They show that Selberg-type integrals can be evaluated by means of Hankel hyperdeterminants, and they prove many hyperdeterminant generalisations of classical Hankel determinant evaluations.

At last, (but certainly not least!), I want to draw the reader’s attention to Lascoux’s “unorthodox” approach to Hankel determinants and orthogonal polynomials through symmetric functions which he presents in detail in [113, Ch. 4, 5, 8]. In particular, Theorem 29, Eq. (5.38) are the contents of Theorem 8.3.1 in [113] (see also the end of Section 5.3 there), and Theorem 30, Eqs. (5.44) and (5.45) are the contents of Theorem 4.2.1 in [113]. The usefulness of this symmetric function approach is, for example, demonstrated in [76, 77] in order to evaluate Hankel determinants of matrices the entries of which are Rogers–Szegő, respectively Meixner polynomials.

5.5. More binomial determinants. A vast part of Section 3 in [103] is occupied by binomial determinants. As I mentioned in Section 2 of the present article, an extremely rich source for binomial determinants is rhombus tiling enumeration. I want to present here some which did not already appear in [103].

To begin with, I want to remind the reader of an old problem posed by Andrews in [11, p. 105]. The determinant in this problem is a variation of a determinant which enumerates cyclically symmetric plane partitions and descending plane partitions, which was evaluated by Andrews in [10] (see also [103, Theorem 32]; the latter determinant arises from the one in (5.68) by replacing $j + 1$ by $j$ in the bottom of the binomial coefficient).

**Problem 34. Evaluate the determinant**

$$D_1(n) := \det_{0 \leq i, j \leq n-1} \left( \delta_{ij} + \left( \mu + i + j \right) \right),$$

(5.68)

where $\delta_{ij}$ is the Kronecker delta. In particular, show that

$$\frac{D_1(2n)}{D_1(2n-1)} = (-1)^{n-1} \frac{2^n \left( \frac{n}{2} + n \right)_{[n/2]} \left( \frac{n}{2} + 2n + \frac{1}{2} \right)_{n-1}}{(n)_{n} \left( \frac{n}{2} - 2n + \frac{3}{2} \right)_{[n-2]/2]},$$

(5.69)

\[22\] It could easily be that it is the “modern” treatment of the theory which must be labelled with the attribute “unorthodox.” As Lascoux documents in [113], in his treatment he follows the tradition of great masters such as Cauchy, Jacobi or Wronski . . .
The determinants $D_i(n)$ are rather intriguing. Here are the first few values:

\[
D_i(1) = \mu + 1, \\
D_i(2) = (\mu + 1)(\mu + 2), \\
D_i(3) = \frac{1}{12}(\mu + 1)(\mu + 2)(\mu + 3)(\mu + 14), \\
D_i(4) = \frac{1}{72}(\mu + 1)(\mu + 2)(\mu + 3)(\mu + 4)(\mu + 9)(\mu + 14), \\
D_i(5) = \frac{1}{8640}(\mu + 1)(\mu + 2)(\mu + 3)(\mu + 4)(\mu + 5)(\mu + 9) \\
\times (3432 + 722\mu + 45\mu^2 + \mu^3), \\
D_i(6) = \frac{1}{518400}(\mu + 1)(\mu + 2)(\mu + 3)(\mu + 4)(\mu + 5)(\mu + 6)(\mu + 8)(\mu + 13) \\
\times (\mu + 15)(3432 + 722\mu + 45\mu^2 + \mu^3), \\
D_i(7) = \frac{1}{870912000}(\mu + 1)(\mu + 2)(\mu + 3)(\mu + 4)(\mu + 5)(\mu + 6)(\mu + 7)(\mu + 8)^2 \\
\times (\mu + 13)(\mu + 15)^2(\mu + 34)(\mu^3 + 47\mu^2 + 954\mu + 5928), \\
D_i(8) = \frac{1}{73156080000}(\mu + 1)(\mu + 2)(\mu + 3)(\mu + 4)(\mu + 5)(\mu + 6)(\mu + 7)(\mu + 8)^3 \\
\times (\mu + 10)(\mu + 15)^2(\mu + 17)(\mu + 19) \\
\times (\mu + 21)(\mu + 34)(\mu^3 + 47\mu^2 + 954\mu + 5928).
\]

"So," these determinants factor almost completely, there is only a relatively small (in degree) irreducible factor which is not linear. (For example, this factor is of degree 6 for $D_i(9)$ and $D_i(10)$, and of degree 7 for $D_i(11)$ and $D_i(12)$.) Moreover, this "bigger" factor is always the same for $D_i(2n - 1)$ and $D_i(2n)$. Not only that, the quotient which is predicted in (5.69) is at the same time a building block in the result of the evaluation of the determinant which enumerates the cyclically symmetric and descending plane partitions (see [11]). All this begs for an explanation in terms of a factorisation of the matrix of which the determinant is taken from. In fact, for the plane partition matrix there is such a factorisation, due to Mills, Robbins and Rumsey [124, Theorem 5] (see also [103, Theorem 36]). The question is whether there is a similar one for the matrix in (5.68).

Inspired by this conjecture and by the variations in [37, Theorems 11-13] (see [103, Theorem 35]) on Andrews’ original determinant evaluation in [10], Guoce Xin (private communication) observed that, if we change the sign in front of the Kronecker delta in (5.68), then the resulting determinant factors completely into linear factors.

**Conjecture 35.** Let $\mu$ be an indeterminate and $n$ be a non-negative integer. The determinant

\[
\det_{0 \leq i, j \leq n-1} \left( -\delta_{ij} + \binom{\mu + i + j}{j + 1} \right)
\]  

(5.70)
is equal to

\[
(-1)^{n/2}2^{n(n+2)/4} \left( \frac{n}{2} \right)^{n/2} \left( \prod_{i=0}^{(n-2)/2} \frac{i^2}{(2i)!} \right) \times \left( \prod_{i=0}^{[(n-1)/4]} \left( \frac{\mu}{2} + 3i + \frac{5}{2} \right)^2 \left( \frac{\mu}{2} - \frac{3n}{2} + 3i + 3 \right)^2 \right)^{(n-4i-2)/2} \]  

(5.71)

if \( n \) is even, and it is equal to

\[
(-1)^{(n-1)/2}2^{(n+3)(n+1)/4} \left( \frac{n-1}{2} \right)^{(n+1)/2} \left( \prod_{i=0}^{(n-1)/2} \frac{(i+1)!}{(2i)! (2i+2)!} \right) \times \left( \prod_{i=0}^{[(n-3)/4]} \left( \frac{\mu}{2} + 3i + \frac{5}{2} \right)^2 \left( \frac{\mu}{2} - \frac{3n}{2} + 3i + 3 \right)^2 \right)^{(n-4i-3)/2} \]  

(5.72)

if \( n \) is odd.

In fact, it seems that also the “next” determinant, the determinant where one replaces \( j+1 \) at the bottom of the binomial coefficient in (5.70) by \( j+2 \) factors completely when \( n \) is odd. (It does not when \( n \) is even, though.)

**Conjecture 36.** Let \( \mu \) be an indeterminate. For any odd non-negative integer \( n \) there holds

\[
\det_{0 \leq i, j \leq n-1} \left( -\delta_{ij} + \binom{\mu + i + j}{j+2} \right) = (-1)^{(n-1)/2}2^{(n-1)(n+5)/4} \left( \mu+1 \right)^{n-1/2} \left( \prod_{i=0}^{(n-1)/2} \frac{i^2}{(2i)!} \left( \mu + 3i + \frac{3}{2} \right)^2 \right)^{(n-4i-1)/2} \times \left( \prod_{i=0}^{[(n-3)/4]} \left( -\frac{\mu}{2} - \frac{3n}{2} + 3i + \frac{5}{2} \right)^2 \right)^{(n-4i-3)/2} . \]  

(5.73)

For the combinatorialist I add that all the determinants in Problem 34 and Conjectures 35 and 36 count certain rhombus tilings, as do the original determinants in [10, 11, 37].

Alain Lascoux (private communication) did not understand why we should stop here, and he hinted at a parametric family of determinant evaluations into which the case of odd \( n \) of Conjecture 35 is embedded as a special case.
Conjecture 37. Let $\mu$ be an indeterminate. For any odd non-negative integers $n$ and $r$ there holds

$$
\det_{0 \leq i,j \leq a-1} \left( -\delta_{i,j+r-1} + \left( \frac{\mu + i + j}{j + r} \right) \right) \\
= (-1)^{(n-r)/2} \frac{n^2 + 6nr + 2r^2 - (r+2)/4}{(\prod_{i=0}^{r-2} (\prod_{i=1}^{r-1} (m - r + i)_{n+r-2i+1}) \prod_{i=0}^{(n-1)/2} \frac{3i+1}{2} (2i)! (2i+2)!)} \times \left( \frac{\mu + 1}{2} \right) \left( \prod_{i=0}^{(n-r)/2} \left( \frac{\mu + 3i + r + 3}{2} \right) \right)^2 \left( \frac{-\frac{3n}{2} + r + 3i + 1}{2} \right)^{\frac{n-4i-r+2}{2}} .
$$

(5.74)

The next binomial determinant that I want to mention is, strictly speaking, not a determinant but a Pfaffian (see (5.4) for the definition). While doing $(-1)$-enumeration of self-complementary plane partitions, Eisenkölbl [54] encountered an, I admit, complicated looking Pfaffian,

$$
Pf_{l \leq i,j \leq a} \left( M(m_1, m_2, n_1, n_2, a, b) \right),
$$

(5.75)

where $a$ is even and $b$ is odd, and where

$$
M_{\bar{g}}(m_1, m_2, n_1, n_2, a, b)
= \sum_{l=1}^{(a+b-1)/4} (-1)^{i+j} \left( \left( \frac{b-1}{2} + \left( \frac{i-1}{2} \right) - l + 1 \right) \left( -\frac{a}{2} + \left( \frac{j-1}{2} \right) + l \right) \right)
- \left( \frac{b-1}{2} + \left( \frac{j-1}{2} \right) - l + 1 \right) \left( -\frac{a}{2} + \left( \frac{i-1}{2} \right) + l \right)
+ \sum_{l=1}^{(a+b-1)/4} \left( \left( \frac{b-1}{2} + \left( \frac{i}{2} \right) - l + 1 \right) \left( -\frac{a}{2} + \left( \frac{j}{2} \right) + l - 1 \right) \right)
- \left( \frac{b-1}{2} + \left( \frac{j}{2} \right) - l + 1 \right) \left( -\frac{a}{2} + \left( \frac{i}{2} \right) + l - 1 \right).
$$

Remarkably however, experimentally this Pfaffian, first of all, factors completely into factors which are linear in the variables $m_1, m_2, n_1, n_2$, but not only that, there seems to be complete separation, that is, each linear factor contains only one of $m_1, m_2, n_1, n_2$. One has the impression that this phenomenon should have an explanation in a factorisation of the matrix in (5.75). However, the task of finding one seems to be not an easy one in view of the “entangledness” of the parameters in the sums of the matrix entries.

Problem 38. Find and prove the closed form evaluation of the Pfaffian in (5.75).
Our next determinants can be considered as shuffles of two binomial determinants. Let us first consider

\[
\det_{1 \leq i, j \leq a + m} \begin{pmatrix}
\binom{b + c + m}{b - i + j} & 1 \leq i \leq a \\
\binom{b + c}{b + a + i + j + \varepsilon} & a + 1 \leq i \leq a + m
\end{pmatrix}.
\]

(5.76)

In fact, if \( \varepsilon = 0 \), and if \( a, b, c \) all have the same parity, then this is exactly the determinant in (2.10), the evaluation of which proves Theorem 3, as we explained in Section 2. If \( \varepsilon = 1/2 \) and \( a \) has parity different from that of \( b \) and \( c \), then the corresponding determinant was also evaluated in [37], and this evaluation implied the companion result to Theorem 3 that we mentioned immediately after the statement of the theorem. In the last section of [37], it is reported that, apparently, there are also nice closed forms for the determinant in (5.76) for \( \varepsilon = 1 \) and \( \varepsilon = 3/2 \), both of which imply as well enumeration theorems for rhombus tilings of a hexagon with an equilateral triangle removed from its interior (see Conjectures 1 and 2 in [37]). We reproduce the conjecture for \( \varepsilon = 1 \) here, the one for \( \varepsilon = 3/2 \) is very similar in form.

**Conjecture 39.** Let \( a, b, c, m \) be non-negative integers, \( a, b, c \) having the same parity. Then for \( \varepsilon = 1 \) the determinant in (5.76) is equal to

\[
\frac{1}{4} H(a + m) H(b + m) H(c + m) H(a + b + c + m) \\
\times H(a + b + m) H(a + c + m) H(b + c + m)
\]

\[
\times \frac{H(m + \binom{a+b+c}{a+b+c}) H(m + \binom{a+b+c}{a+b+c})}{H(\binom{a+b+c}{a+b+c}) H(\binom{a+b+c}{a+b+c}) H(\binom{a+b+c}{a+b+c}) H(\binom{a+b+c}{a+b+c})}
\]

\[
\times \frac{H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}})}{H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}})}
\]

\[
\times \frac{H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}})}{H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}}) H(\binom{m}{\frac{a+b+c}{a+b+c}})}
\]

\[
P_1(a, b, c, m),
\]

(5.77)

where \( P_1(a, b, c, m) \) is the polynomial given by

\[
P_1(a, b, c, m) = \begin{cases} 
(a + b)(a + c) + 2am & \text{if } a \text{ is even,} \\
(a + b)(a + c) + 2(a + b + c + m)m & \text{if } a \text{ is odd,}
\end{cases}
\]

and where \( H(n) \) is the hyperfactorial defined in (2.8).

Two other examples of determinants in which the upper part is given by one binomial matrix, while the lower part is given by a different one, arose in [40, Conjectures A.1 and A.2]. Again, both of them seem to factor completely into linear factors, and both of them imply enumeration results for rhombus tilings of a certain V-shaped region. The right-hand sides of the (conjectured) results are the weirdest “closed” forms in enumeration that I am aware of.\(^{23}\) We state just the first of the two conjectures, the other is very similar.

\(^{23}\) No non-trivial simplifications seem to be possible.
Conjecture 40. Let \( x, y, m \) be non-negative integers. Then the determinant
\[
\det_{1 \leq i, j \leq m+y} \left( \begin{array}{c} \binom{x+i}{i} \\ \binom{x+i-j}{i-m-y+2-2i-j+1} \end{array} \right)_{i = 1, \ldots, m} \left( \begin{array}{c} \binom{x+i-j}{i-m-y+2-2i-j+1} \end{array} \right)_{i = m+1, \ldots, m+y}.
\] (5.78)
is equal to
\[
\prod_{i=1}^{m} \frac{(x+i)!}{(x-i+m+y+1)!} \prod_{i=m+1}^{m+y} \frac{(x+2m-i+1)!}{(2m+2y-2i+1)! (m+x-y+i-1)!} \nonumber
\]
\[
\times 2 \binom{m}{y} \prod_{i=1}^{m-1} \prod_{j=0}^{y-1} \left( x + i + \frac{3}{2} \right)_{m-2i-1} \left( x - y + \frac{5}{2} + 3i \right)_{-\frac{y}{2} - \frac{y}{2}}
\]
\[
\times \prod_{i \geq 0} \left( x + m - \left[ \frac{y}{2} \right] + i + 1 \right)_{\left[ \frac{y}{2} \right] - \left[ \frac{y}{2} \right]} \prod_{i \geq 0} \left( x + \left[ \frac{y}{2} \right] + i + 2 \right)_{m-2i} \nonumber
\]
\[
\times \frac{\prod_{i=0}^{y} \left( x - y + 3i + 1 \right)_{m+2y-4i} \left[ \frac{y}{2} \right]_{-1}}{\prod_{i=0}^{y} \left( x + m - y + i + 1 \right)_{3y-m-4i}}
\]
\[
\times \prod_{i \geq 0} \left( x + \frac{m}{2} - \frac{y}{2} + i + 1 \right)_{y-2i} \left( x + \frac{m}{2} - \frac{y}{2} + i + \frac{3}{2} \right)_{y-2i-1}
\]
\[
\times \frac{\prod_{i=0}^{y} (x+i+2)_{2m-2i-1}}{\prod_{i=0}^{y} (x+y+2)_{m-y+1} (m+x-y+1)_{m+y}}.
\] (5.79)

Here, shifted factorials occur with positive as well as with negative indices. The convention with respect to which these have to be interpreted is
\[
(\alpha)_k := \begin{cases} 
\alpha(\alpha+1) \cdots (\alpha+k-1) & \text{if } k > 0, \\
1 & \text{if } k = 0, \\
1/(\alpha-1)(\alpha-2) \cdots (\alpha+k) & \text{if } k < 0.
\end{cases}
\]

All products \( \prod_{i \geq 0} (f(i))_{g(i)} \) in (5.79) have to interpreted as the products over all \( i \geq 0 \) for which \( g(i) \geq 0 \).

For further conjectures of determinants of shuffles of two binomial matrices I refer the reader to Conjectures 1–3 in Section 4 of [65]. All of them imply also enumeration results for rhombus tilings of hexagons. This time, these would be results about the number of rhombus tilings of a symmetric hexagon with some fixed rhombi on the symmetry axis.

### 5.6. Determinants of Matrices with Recursive Entries

Binomial coefficients \( \binom{i+j}{i} \) satisfy the basic recurrence of the Pascal triangle,
\[
p_{i,j} = p_{i,j-1} + p_{i-1,j}.
\] (5.80)

We have seen many determinants of matrices with entries containing binomial coefficients in the preceding subsection and in [103, Sec. 3]. In [17], Bacher reports an
experimental study of determinants of matrices \((p_{ij})_{0 \leq i,j \leq n-1}\), where the coefficients \(p_{ij}\) satisfy the recurrence (5.80) (and sometimes more general recurrences), but where the initial conditions for \(p_{i0}\) and \(p_{0i}, \ i \geq 0\), are different from the ones for binomial coefficients. He makes many interesting observations. The most intriguing one says that these determinants satisfy also a linear recurrence (albeit a much longer one). It is intriguing because it points towards the possibility of automatising determinant evaluations\(^\text{24}\), something that several authors (cf. e.g. [9, 103, 135]) have been aiming at (albeit, with only limited success up to now). The conjecture (and, in fact, a generalisation thereof) has been proved by Petkovšek and Zakrjsek in [184]. Still, there remains a large gap to fill until computers will replace humans doing determinant evaluations.

The paper [17] contained as well several pretty conjectures on closed form evaluations of special cases of such determinants. These were subsequently proved in [105]. We state three of them in the following three theorems. The first two are proved in [105] by working out the LU-factorisation (see “Method 1” in Section 4) for the matrices of which the determinant is computed. The third one is derived by simple row and column operations.

**Theorem 41.** Let \((a_{ij})_{i,j \geq 0}\) be the sequence given by the recurrence
\[
a_{ij} = a_{i-1,j} + a_{i,j-1} + x a_{i-1,j-1}, \quad i, j \geq 1,
\]
and the initial conditions \(a_{i0} = \rho^i\) and \(a_{0i} = \sigma^i, \ i \geq 0\). Then
\[
\det_{0 \leq i,j \leq n-1} (a_{ij}) = (1 + x)^{(n-1)}(x + \rho - \rho \sigma)^{n-1}.
\] (5.81)

**Theorem 42.** Let \((a_{ij})_{i,j \geq 0}\) be the sequence given by the recurrence
\[
a_{ij} = a_{i-1,j} + a_{i,j-1} + x a_{i-1,j-1}, \quad i, j \geq 1,
\]
and the initial conditions \(a_{i0} = 0, \ i \geq 0\), \(a_{i0} = \rho^i\) and \(a_{0i} = -\rho^{-i}, \ i \geq 1\). Then
\[
\det_{0 \leq i,j \leq 2n-1} (a_{ij}) = (1 + x)^{2(n-1)^2}(x + \rho)^{2n-2}.
\] (5.82)

**Theorem 43.** Let \((a_{ij})_{i,j \geq 0}\) be the sequence given by the recurrence
\[
a_{ij} = a_{i-1,j} + a_{i,j-1} + x a_{i-1,j-1}, \quad i, j \geq 1,
\]
and the initial conditions \(a_{i0} = i\) and \(a_{0i} = -i, \ i \geq 0\). Then
\[
\det_{0 \leq i,j \leq 2n-1} (a_{ij}) = (1 + x)^{2n(n-1)}.
\] (5.83)

Certainly, the proofs in [105] are not very illuminating. Neuwirth [130] has looked more carefully into the structure of recursive sequences of the type as those in Theorems 41–43. Even more generally, he looks at sequences \((f_{ij})_{i,j \geq 0}\) satisfying the recurrence relation
\[
f_{ij} = c_j f_{i-1,j} + d_j f_{i,j-1} + e_j f_{i-1,j-1}, \quad i, j \geq 1,
\] (5.84)

\(^{24}\)The reader should recall that the successful automatisation [136, 180, 182, 186, 187] of the evaluation of binomial and hypergeometric sums is fundamentally based on producing recurrences by the computer.
for some given sequences \((c_j)_{j \geq 1}, (d_j)_{j \geq 1}, (e_j)_{j \geq 1}\). He approaches the problem by finding appropriate matrix decompositions for the (infinite) matrix \((f_{ij})_{i,j \geq 0}\). In two special cases, he is able to apply his decomposition results to work out the LU-factorisation of the matrix \((f_{ij})_{i,j \geq 0}\) explicitly, which then yields an elegant determinant evaluation in both of these cases. Neuwirth’s first result [130, Theorem 5] addresses the case where the initial values \(f_{0,j}\) satisfy a first order recurrence determined by the coefficients \(d_j\) from (5.84). It generalises Theorem 41. There is no restriction on the initial values \(f_{i,0}\) for \(i \geq 1\).

**Theorem 44.** Let \((c_j)_{j \geq 1}, (d_j)_{j \geq 1}\) and \((e_j)_{j \geq 1}\) be given sequences, and let \((f_{ij})_{i,j \geq 0}\) be the doubly indexed sequence given by the recurrence (5.84) and the initial conditions \(f_{0,0} = 1\) and \(f_{0,j} = d_j f_{0,j-1}, j \geq 1\). Then

\[
\det_{0 \leq i,j \leq n-1} (f_{i,j}) = \prod_{0 \leq i < j \leq n-1} (e_{i+1} + c_j d_{i+1}).
\]  

(5.85)

Neuwirth’s second result [130, Theorem 6] also generalises Theorem 41, but in a different way. This time, the initial values \(f_{0,j}, j \geq 1\), are free, whereas the initial values \(f_{i,0}\) satisfy a first order recurrence determined by the coefficients \(c_j\) from the recurrence (5.84). Below, we state its most attractive special case, in which all the \(c_j\)’s are identical.

**Theorem 45.** Let \((d_j)_{j \geq 1}\) and \((e_j)_{j \geq 1}\) be given sequences, and let \((f_{ij})_{i,j \geq 0}\) be the doubly indexed sequence given by the recurrence (5.84) and the initial conditions \(f_{0,0} = 1\) and \(f_{i,0} = c f_{i-1,0}, i \geq 1\). Then

\[
\det_{0 \leq i,j \leq n-1} (f_{i,j}) = \prod_{i=1}^{n-1} (\alpha d_i + e_i)^{n-i}.
\]  

(5.86)

5.7. Determinants for signed permutations. The next class of determinants that we consider are determinants of matrices in which rows and columns are indexed by elements of reflection groups (the latter being groups generated by reflections of hyperplanes in real \(n\)-dimensional space; see [78] for more information on these groups, and, more generally, on Coxeter groups). The prototypical example of a reflection group is the symmetric group \(S_n\), of permutations of an \(n\)-element set. In [103], there appeared two determinant evaluations associated to the symmetric group, see Theorems 55 and 56 in [103]. They concerned evaluations of determinants of the type

\[
\det_{\sigma \tau \in S_n} \left(q^{\text{stat}(\sigma \tau^{-1})}\right),
\]  

(5.87)
due to Varchenko, Zagier, and Thibon, respectively, in which \(\text{stat}\) is the statistic “number of inversions,” respectively “major index.” We know that in many fields of mathematics there exist certain diseases which are typical for that field. Algebraic combinatorics is no exception. Here, I am not talking of the earlier mentioned “q-disease” (see Footnote 20; although, due to the presence of \(q\) we might also count it as a case of \(q\)-disease), but of the disease which manifests itself by the question “And what about
the other types?" \footnote{In order to give a reader who is not acquainted with the language and theory of reflection groups an idea what this question is referring to, I mention that all finite reflection groups have been classified, each having been assigned a certain “type.” So, usually one proves something for the symmetric group $S_n$, which, according to this classification, has type $A_{n-1}$, and then somebody (which could be oneself) will ask the question “Can you also do this for the other types?”, meaning whether or not there exists an analogous result for the other finite reflection groups.} So let us ask this question, that is, are there theorems similar to the two theorems which we mentioned above for other reflection groups?

So, first of all we need analogues of the statistics “number of inversions” and “major index” for other reflection groups. Indeed, these are available in the literature. The analogue of “number of inversions” is the so-called \textit{length} of an element in a Coxeter group (see [78] for the definition). As a matter of fact, a closed form evaluation of the determinant \eqref{eq:det}, where $S_n$ is replaced by any finite or affine reflection group, and where sat is the length, is known (and was already implicitly mentioned in \cite{103}). This result is due to Varchenko \cite[Theorem (1.1)]{176}, where $a(H)$ is specialised to $q$. His result is actually much more general, as it is valid for real hyperplane arrangements in which each hyperplane is assigned a different weight. I will not state it here explicitly because I do not want to go through the definitions and notations which would be necessary for doing that.

So, what about analogues of the “major index” for other reflection groups? These are also available, and there are in fact several of them. The first person to introduce a major index for reflection groups other than the symmetric groups was Reiner in \cite{142}. He proposed a major index for the \textit{hyperoctahedral group} $B_n$, which arose naturally in his study of $P$-\textit{partitions for signed posets}. The elements of $B_n$ are often called \textit{signed permutations}, and they are all elements of the form $\pi_1\pi_2\ldots\pi_n$, where $\pi_i \in \{\pm 1, \pm 2, \ldots, \pm n\}$, $i = 1, 2, \ldots, n$, and where $|\pi_1||\pi_2|\ldots|\pi_n|$ is a permutation in $S_n$. To define their multiplicative structure, it is most convenient to view $\pi = \pi_1\pi_2\ldots\pi_n$ as a linear operator on $\mathbb{R}^n$ acting by permutation and sign changes of the coordinates. To be precise, the action is given by $\pi(e_i) = (\operatorname{sgn}\pi_i)e_{|\pi_i|}$, where $e_i$ is the $i$-th standard basis vector in $\mathbb{R}^n$, $i = 1, 2, \ldots, n$. The multiplication of two signed permutations is then simply the composition of the corresponding linear operators.

The major index $\operatorname{maj}_B \pi$ of an element $\pi \in B_n$ which Reiner defined is, as in the symmetric group case, the sum of all positions of \textit{descents} in $\pi$. (There is a natural notion of “descent” for any Coxeter group.) Concretely, it is

$$\operatorname{maj}_B \pi := \chi(\pi_n < 0) + \sum_{i=1}^{n-1} i \cdot \chi(\pi_i >_B \pi_{i+1}),$$

where we impose the order $1 <_B 2 <_B \cdots <_B n <_B -n <_B \cdots <_B -2 <_B -1$ on our ground set $\{\pm 1, \pm 2, \ldots, \pm n\}$, and where $\chi(\mathcal{A}) = 1$ if $\mathcal{A}$ is true and $\chi(\mathcal{A}) = 0$ otherwise.
There is overwhelming computational evidence\textsuperscript{26} that the “major-determinant” for $B_n$, i.e., the determinant (5.87) with $\text{stat} = \text{maj}_B$ and with $\mathfrak{S}_n$ replaced by $B_n$, factors completely into cyclotomic polynomials.

**Conjecture 46.** For any positive integer $n$, we have

$$\det_{\sigma, \pi \in B_n} \left( q^{\text{maj}_B(\sigma \pi^{-1})} \right) = \prod_{i=1}^{n} (1 - q^{2^i})^{\text{maj}_A(\sigma \pi^{-1})} \prod_{i=2}^{n} (1 - q^{i})^{2^{n-i}(i-1)/i}. \quad (5.88)$$

A different major index for $B_n$ was proposed by Adin and Roichman in [3]. It arises there naturally in a combinatorial study of polynomial algebras which are diagonally invariant under $B_n$. (In fact, more generally, wreath products of the form $C_m \wr \mathfrak{S}_n$, where $C_m$ is the cyclic group of order $m$, and their diagonal actions on polynomial algebras are studied in [3]. These groups are also sometimes called generalised reflection groups. In this context, $B_n$ is the special case $C_2 \wr \mathfrak{S}_n$.) If we write $\text{neg} \, \pi$ for the number of $i$ for which $\pi_i$ is negative, then the flag-major index $\text{fmaj}$ of Adin and Roichman is defined by

$$\text{fmaj} \, \pi := 2 \text{maj}_A \, \pi + \text{neg} \, \pi, \quad (5.89)$$

where $\text{maj}_A$ is the “ordinary” major index due to MacMahon,

$$\text{maj}_A \, \pi := \sum_{i=1}^{n-1} i \cdot \chi(\pi_i > \pi_{i+1}).$$

If one now goes to the computer and calculates the determinant on the left-hand side of (5.88) with $\text{maj}_B$ replaced by $\text{fmaj}$ for $n = 1, 2, 3, 4, 5$ (see Footnote \textsuperscript{26} for the precise

\textsuperscript{26}The reader may wonder what this computational evidence could actually be. After all, we are talking about a determinant of a matrix of size $2^n n!$. More concretely, for $n = 1, 2, 3, 4, 5$ these are matrices of size 2, 8, 48, 384, 3840, respectively. While Maple or Mathematica have no problem to compute these determinants for $n = 1$ and $n = 2$, it takes already considerable time to do the computation for $n = 3$, and it is, of course, completely hopeless to let them compute the one for $n = 4$, a determinant of a matrix of size 384 which has polynomial entries (cf. Footnote 18). However, the results for $n = 1, 2, 3$ already “show” that the determinant will factor completely into factors of the form $1 - q^i$, $i = 1, 2, \ldots, 2n$. One starts to expect the same to be true for higher $n$. To get a formula for $n = 4$, one would then apply the tricks explained in Footnote 19. That is, one specialises $q$ to 4, at which value the first 8 cyclotomic polynomials (in fact, even more) are clearly distinguishable by their prime factorisations, and one computes the determinant. The exponents of the various factors $1 - q^i$ can then be extracted from the exponents of the prime factors in the prime factorisation of the determinant with $q = 4$. Unfortunately, the data collected for $n = 1, 2, 3, 4$ do not suffice to come up with a guess, and, on the other hand, Maple and Mathematica will certainly be incapable to compute a determinant of a matrix of size 3840 (which, just to store it on the disk, occupies already 10 megabytes ...). So then, did I mean when I said that the conjecture is based on data including $n = 5$? This turned out to become a “test case” for LinBox, a C++ template library for exact high-performance linear algebra [49], which is freely available under http://linalg.org. To be honest, I was helped by Dave Saunders and Zhendong Wan (two of the developers) who applied LinBox to do rank and Smith normal form computations for the specialised matrix with respect to various prime powers (each of which taking several hours). The specific computational approach that worked here is quite recent (thus, it came just in time for our purpose), and is documented in [152]. The results of the computations made it possible to come up with a “sure” prediction for the exponents with which the various prime factors occur in the prime factorisation of the specialised determinant. As in the case $n = 4$, the exponents of the various factors $1 - q^i$, $i = 1, 2, \ldots, 2n$ can then easily be extracted. (The guesses were subsequently also tested with special values of $q$ other than $q = 4$.)
meaning of “calculating the determinant for \( n = 1, 2, 3, 4, 5 \)”, then again the results factor completely into cyclotomic factors. Even more generally, it seems that one can treat the two parts on the right-hand side of (5.89), that is “major index” and “number of negative letters,” separately.

**Conjecture 47.** For any positive integer \( n \), we have

\[
\det_{\sigma, \pi \in B_n} \left( q^{\text{maj}_4(\sigma) - 1} p^{\text{neg}(\sigma^{-1})} \right) = \prod_{i=1}^{n} (1 - p^{2^i})^{2^{n-i}/i} \prod_{i=2}^{n} (1 - q^i)^{2^n n!(i-1)/i}. \tag{5.90}
\]

I should remark that Adin and Roichman have shown in [3] that the statistics \( \text{fmaj} \) is equidistributed with the statistics length on \( B_n \). However, even in the case where we just look at the flag-major determinant (that is, the case where \( q = p^2 \) in Conjecture 47), this does not seem to help. (Neither length nor flag-major index satisfy a simple law with respect to multiplication of signed permutations.) In fact, from the data one sees that the flag-major determinants are different from the length determinants (that is, the determinants (5.87), where \( \mathcal{S}_n \) is replaced by \( B_n \) and stat is flag-major, respectively length).

Initially, I had my program wrong, and, instead of taking the (ordinary) major index \( \text{maj}_4 \) of the signed permutation \( \pi = \pi_1 \pi_2 \ldots \pi_n \) in (5.89), I computed taking the major index of the absolute value of \( \pi \). This absolute value is obtained by forgetting all signs of the letters of \( \pi \), that is, writing \( |\pi| \) for the absolute value of \( \pi \), \( |\pi| = |\pi_1| |\pi_2| \ldots |\pi_n| \). Curiously, it seems that also this “wrong” determinant factors nicely. (Again, the evidence for this conjecture is based on data which were obtained in the way described in Footnote 26.)

**Conjecture 48.** For any positive integer \( n \), we have

\[
\det_{\sigma, \pi \in B_n} \left( q^{\text{maj}(\sigma) - 1} p^{\text{neg}(\sigma^{-1})} \right) = (1 - p^2)^{2^{n-1} n!} \prod_{i=2}^{n} (1 - q^i)^{2^n n!(i-1)/i}. \tag{5.91}
\]

Since, as I indicated earlier, Adin and Roichman actually define a flag-major index for wreath products \( C_m \wr \mathcal{S}_n \), a question that suggests itself is whether or not we can expect closed product formulae for the corresponding determinants. Clearly, since we are now dealing with determinants of the size \( m^n n! \), computer computations will exhaust our computer’s resources even faster if \( m > 2 \). The calculations that I was able to do suggest strongly that there is indeed an extension of the statement in Conjecture 47 to the case of arbitrary \( m \), if one uses the definition of major index and the “negative” statistics for \( C_m \wr \mathcal{S}_n \) as in [3]. (See [3, Section 3] for the definition of the major index. The sum on the right-hand side of (3.1) must be taken as the extension of the “negative” statistics \( \text{neg} \) to \( C_m \wr \mathcal{S}_n \).)

**Problem 49.** Find and prove the closed form evaluation of

\[
\det_{\sigma, \pi \in C_m \wr \mathcal{S}_n} \left( q^{\text{maj}(\sigma) - 1} p^{\text{neg}(\sigma^{-1})} \right), \tag{5.92}
\]

where \( \text{maj} \) and \( \text{neg} \) are the extensions to \( C_m \wr \mathcal{S}_n \) of the statistics \( \text{maj}_4 \) and \( \text{neg} \) in Conjecture 47, as described in the paragraph above.

Together with Brenti, Adin and Roichman proposed another major statistics for signed permutations in [1]. They call it the **negative major index**, denoted \( \text{nmaj} \), and...
it is defined as the sum of the ordinary major index and the sum of the absolute values of the negative letters, that is,

$$\text{nmaj} \pi := \text{maj}_A \pi + \text{sneg} \pi,$$

where \( \text{sneg} \pi := -\sum_{i=1}^n \chi(\pi_i < 0) \pi_i \). Also for this statistics, the corresponding determinant seems to factor nicely. In fact, it seems that one can again treat the two components of the definition of the statistics, that is, "major index" and "sum of negative letters," separately. (Once more, the evidence for this conjecture is based on data which were obtained in the way described in Footnote 26.)

**Conjecture 50.** For any positive integer \( n \), we have

$$
\det_{\sigma, \pi \in B_n} \left( q^{\text{maj}_A(\pi^{-1})} p^{\text{sneg}(\pi^{-1})} \right) = \prod_{i=1}^n (1 - p^{2^i}) 2^{n-1} i \prod_{i=2}^n (1 - q^i)^{2^{n-1} i (i-1)/i}. \tag{5.93}
$$

If one compares the (conjectured) result with the (conjectured) one for the "flag-major determinant" in Conjecture 47, then one notices the somewhat mind-boggling fact that one obtains the right-hand side of (5.93) from the one of (5.90) by simply replacing (in the factored form of the latter) \( 1 - p^{2^i} \) by \( 1 - p^{2^i} \), everything else, the "\( q \)-part," is identical. It is difficult to imagine an intrinsic explanation why this should be the case.

Since Thibon’s proof of the evaluation of the determinant (5.87) with stat being the (ordinary) major index for permutations (see [103, Appendix C]) involved the descent algebra of the symmetric group, viewed in terms of non-commutative symmetric functions, one might speculate that to prove Conjectures 46–48 and 50 it may be necessary to work with \( B_n \) versions of descent algebras (which exist, see [167]) and non-commutative symmetric functions (which also exist, see [29]).

For further work on statistics for (generalised) reflection groups (thus providing further prospective candidates for forming interesting determinants), I refer the reader to [1, 2, 18, 22, 23, 25, 26, 60, 73, 141]. I must report that, somewhat disappointingly, it seems that the various major indices proposed for the group \( D_n \) of even signed permutations (see [25, 26, 142]) apparently do not give rise to determinants in the same way as above that have nice product formulæ. This remark seems to also apply to determinants formed in an analogous way by using the various statistics proposed for the alternating group in [140].

**5.8. More poset and lattice determinants.** Continuing the discussion of determinants which arise under the influence of the above-mentioned "reflection group disease," we turn our attention to two miraculous determinants which were among the last things Rodica Simion was able to look at. Some of her considerations in this direction are reported in [157].

The first of the two is a determinant of a matrix the rows and columns of which are indexed by type \( B \) non-crossing partitions. This determinant is inspired by the evaluation of an analogous one for ordinary non-crossing partitions (that is, in "reflection group language," type \( A \) non-crossing partitions), due to Dahab [47] and Tutte [175] (see [103, Theorem 57, (3.69)]). Recall (see [169, Ch. 1 and 3] for more information) that a (set) partition of a set \( S \) is a collection \( \{B_1, B_2, \ldots, B_k\} \) of pairwise disjoint non-empty subsets of \( S \) such that their union is equal to \( S \). The subsets \( B_i \) are also called
blocks of the partition. One partially orders partitions by refinement. With respect to
this partial order, the partitions form a lattice. We write $\pi \vee_A \gamma$ (the $A$ stands for the
fact that, in “reflection group language”, we are looking at “type A partitions”) for
the join of $\pi$ and $\gamma$ in this lattice. Roughly speaking, the join of $\pi$ and $\gamma$ is formed by
considering altogether all the blocks of $\pi$ and $\gamma$. Subsequently, whenever we find two
blocks which have a non-empty intersection, we merge them into a bigger block, and
we keep doing this until all the (merged) blocks are pairwise disjoint.

If $S = \{1, 2, \ldots, n\}$, we call a partition non-crossing if for any $i < j < k < l$ the
elements $i$ and $k$ are in the same block at the same time as the elements $j$ and $l$ are in
the same block only if these two blocks are the same. (I refer the reader to [160] for a
survey on non-crossing partitions.)

Reiner [143] introduced non-crossing partitions in type $B$. Partitions of type $B_n$ are
(ordinary) partitions of $\{1, 2, \ldots, n, -1, -2, \ldots, -n\}$ with the property that whenever
$B$ is a block then so is $-B := \{-b : b \in B\}$, and that there is at most one block $B$ with
$B = -B$. A block $B$ with $B = -B$, if present, is called the zero-block of the partition.
We denote the set of all type $B_n$ partitions by $\Pi_n^B$, the number of zero blocks of a
partition $\pi$ by $\text{zbk} \, \pi$, and we write $\text{nzbk} \, \pi$ for half of the number of the non-zero blocks.
Type $B_n$ non-crossing partitions are a subset of type $B_n$ partitions. Imposing the order
$1 < 2 < \cdots < n < -1 < -2 < \cdots < -n$ on our ground-set, the definition of type
$B_n$ non-crossing partitions is identical with the one for type $A$ non-crossing partitions,
that is, given this order on the ground-set, a $B_n$ partition is called non-crossing if for
any $i < j < k < l$ the elements $i$ and $k$ are in the same block at the same time as the
elements $j$ and $l$ are in the same block only if these two blocks are the same. We write
$\text{NC}_n^B$ for the set of all $B_n$ non-crossing partitions.

The determinant defined by type $B_n$ non-crossing partitions that Simion tried to
evaluate was the one in (5.94) below.\footnote{In fact, instead of $\vee_A$, the “ordinary” join, she used the join in the type $B_n$ partition lattice $\Pi_n^B$.
However, the number of non-zero blocks will be the same regardless of whether we take the join of
two type $B_n$ non-crossing partitions with respect to “ordinary” join or with respect to “type $B_n$” join.
This is in contrast to the numbers of zero blocks, which can differ largely. (To be more precise, one
way to form the “type $B_n$” join is to first form the “ordinary” join, and then merge all zero blocks
into one big block.) The reason that I insist on using $\vee_A$ is that this is crucial for the more general
Conjecture 52. To tell the truth, the discovery of the latter conjecture is due to a programming error
on my behalf (that is, originally I aimed to program the “type $B'$ join, but it happened to be the
“ordinary” join \ldots).} The use of the “type $A$” join $\vee_A$ for two

\begin{align*}
\begin{split}
\text{The determinant defined by type\hspace{1em} type $B_n$ non-crossing partitions that Simion tried to evaluate was the one in (5.94) below.\footnote{In fact, instead of $\vee_A$, the “ordinary” join, she used the join in the type $B_n$ partition lattice $\Pi_n^B$. However, the number of non-zero blocks will be the same regardless of whether we take the join of two type $B_n$ non-crossing partitions with respect to “ordinary” join or with respect to “type $B_n$” join. This is in contrast to the numbers of zero blocks, which can differ largely. (To be more precise, one way to form the “type $B_n$” join is to first form the “ordinary” join, and then merge all zero blocks into one big block.) The reason that I insist on using $\vee_A$ is that this is crucial for the more general Conjecture 52. \end{split}
\end{align*}
which are Chebyshev polynomials. Based on some additional numerical calculations, I propose the following conjecture.

**Conjecture 51.** For any positive integer \( n \), we have

\[
\det_{\pi, \gamma \in NC_n} \left( q^{\text{stab}(\pi \vee A_\gamma)} \right) = \prod_{i=1}^{n} \left( \frac{U_{3i-1}(\sqrt{q}/2)}{U_{i-1}(\sqrt{q}/2)} \right)^{\binom{2n}{n-i}},
\]

where \( U_m(x) := \sum_{j \geq 0} (-1)^j \binom{m-j}{j} (2x)^{m-2j} \) is the \( m \)-th Chebyshev polynomial of the second kind.

If proved, this would solve Problem 1 in [157]. It would also solve Problem 2 from [157], because \( U_{n-1}(\sqrt{q}/2) \) is, up to multiplication by a power of \( q \), equal to the product \( \prod_{j \in \mathbb{N}} f_j(q) \), where the polynomials \( f_j(q) \) are the ones of [157]. A simple computation then shows that, when the right-hand side product of (5.94) is expressed in terms of the \( f_j(q) \)'s, one obtains

\[
\prod_{k=1}^{n} f_{sk}(q)^{e_{n,k}},
\]

where

\[
e_{n,k} = \sum_{\ell \neq 0 (\text{mod } 3)} \binom{-n}{n-k} \binom{2n}{n-\ell k}.
\]

This agrees with the data in [157] and with the further ones I have computed (see Footnote 28).

Even more seems to be true. The following conjecture predicts the evaluation of the more general determinant where we also keep track of the zero blocks.

**Conjecture 52.** For any positive integer \( n \), we have

\[
\det_{\pi, \gamma \in NC_n} \left( q^{\text{stab}(\pi \vee A_\gamma)} z^{\text{stab}(\pi \vee A_\gamma)} \right) = z^{\frac{1}{2}\binom{2n}{n}} \prod_{i=1}^{n} \left( 2T_{2i}(\sqrt{q}/2) + 2 - z \right)^{\binom{2n}{n-i}},
\]

where \( T_m(x) := \frac{1}{2} \sum_{j \geq 0} (-1)^j \binom{m-j}{j} (2x)^{m-2j} \) is the \( m \)-th Chebyshev polynomial of the first kind.

---

28Evidently, more than five years later, thanks to technical progress since then, one can go much farther when doing computer calculations. The evidence for Conjecture 51 which I have is based on, similar to the conjectures and calculations on determinants for signed permutations in Subsection 5.7 (see Footnote 26), the exact form of the determinants for \( n = 1, 2, 3, 4 \), which were already computed by Simion, and, essentially, the exact form of the determinants for \( n = 5 \) and 6. By “essentially” I mean, as earlier, that I computed the determinant for many special values of \( q \), which then let me make a guess on the basis of comparison of the prime factors in the factorised results with the prime factors of the candidate factors, that is the irreducible factors of the Chebyshev polynomials. Finally, for guessing the general form of the exponents, the available data were not sufficient for rate (see Footnote 4). So I consulted the fabulous On-Line Encyclopedia of Integer Sequences (http://www.research.att.com/~njas/sequences/Seis.html), originally created by Neil Sloane and Simon Plouffe [165], and since many years continuously further developed by Sloane and his team [164]. An appropriate selection from the results turned up by the Encyclopedia then led to the exponents on the right-hand side of (5.94).
Again, the conjecture is supported by extensive numerical calculations. It is not too difficult to show, by using some identities for Chebyshev polynomials, that Conjecture 52 implies Conjecture 51.

The other determinant which Simion looked at (cf. [157, Problem 9ff]), was the $B_n$ analogue of a determinant of a matrix the rows and columns of which are indexed by non-crossing matchings, due to Lickorish [116], and evaluated by Ko and Smolinsky [95] and independently by Di Francesco [62] (see [103, Theorem 58]). As we may regard (ordinary) non-crossing matchings as partitions all the blocks of which consist of two elements, we define a $B_n$ non-crossing matching to be a $B_n$ non-crossing partition all the blocks of which consist of two elements. We shall be concerned with $B_{2n}$ non-crossing matchings, which we denote by NCmatch(2n). With this notation, the following seems to be true.

**Conjecture 53.** For any positive integer $n$, we have

$$\det_{x, \gamma \in \text{NCmatch}(2n)} \left( q^{z \text{match}(x \vee \gamma)} z^{z \text{match}(x \wedge \gamma)} \right) = \prod_{k=1}^{n} \left( 2T_{2k}(q/2) + 2 - z^2 \right)^{\binom{2n}{2k}}. \quad (5.97)$$

The reader should notice the remarkable fact that, in the case that Conjectures 52 and 53 are true, the right-hand side of (5.97) is, up to a power of $z$, equal to the right-hand side of (5.96) with $q$ replaced by $q^2$ and $z$ replaced by $z^2$. An intrinsic explanation why this should be the case is not known. An analogous relation between the determinants of Tutte and of Lickorish, respectively, was observed, and proved, in [44]. Also here, no intrinsic explanation is known.

The reader is referred to [157] for further open problems related to the determinants in Conjectures 51–53. Finally, it may also be worthwhile to look at determinants defined using $D_n$ non-crossing partitions and non-crossing matchings, see [16] and [143] for two possible definitions of those.

The reader may have wondered why in Conjectures 51 and 52 we considered determinants defined by type $B_n$ non-crossing partitions, which form in fact a lattice, but used the extraneous type $A$ join in the definition of the determinant, instead of the join which is intrinsic to the lattice of type $B_n$ non-crossing partitions. In particular, what would happen if we would make the latter choice? As it turns out, for that situation there exists an elegant general theorem due to Lindström [117], which I missed to state in [103]. I refer to [169, Ch. 3] for the explanation of the poset terminology used in the statement.

**Theorem 54.** Let $L$ be a finite meet semilattice, $R$ be a commutative ring, and $f : L \times L \to R$ be an incidence function, that is, $f(x, y) = 0$ unless $x \wedge y = x$. Then

$$\det_{x, y \in L} \left( f(x \wedge y, x) \right) = \prod_{y \in L} \left( \sum_{x \in L} \mu(x, y) f(x, y) \right), \quad (5.98)$$

where $\mu$ is the Möbius function of $L$. \hfill $\square$

Clearly, this does indeed answer our question, we just have to specialise $f(x, y) = h(x)$ for $x \wedge y = x$, where $h$ is some function from $L$ to $R$. The fact that the above theorem

---

29 and not even the one in the type $A$ non-crossing partition lattice!
talks about meets instead of joins is of course no problem because this is just a matter of convention.

Having an answer in such a great generality, one is tempted to pose the problem of finding a general theorem that would encompass the above-mentioned determinant evaluations due to Tutte, Dahab, Ko and Smolinsky, Di Francesco, as well as Conjectures 51 and 52. This problem is essentially Problem 6 in [157].

**Problem 55.** Let \( L \) and \( L' \) be two lattices (semilattices?) with \( L' \subseteq L \). Furthermore, let \( R \) be a commutative ring, and let \( f \) be a function from \( L \) to \( R \). Under which conditions is there a compact formula for the determinant

\[
\det_{x,y \in L'} \left( f(x \wedge_L y) \right),
\]

where \( \wedge_L \) is the meet operation in \( L' \)?

By specialisation in Theorem 54, one can derive numerous corollaries. For example, a very attractive one is the evaluation of the “GCD determinant” due to Smith [166]. (In fact, Smith’s result is a more general one for factor closed subsets of the positive integers.)

**Theorem 56.** For any positive integer \( n \), we have

\[
\det_{1 \leq i, j \leq n} \left( \gcd(i,j) \right) = \prod_{i=1}^{n} \phi(i),
\]

where \( \phi \) denotes the Euler totient function.

An interesting generalisation of Theorem 54 to posets was given by Altinişık, Sagan and Tuğlu [6]. Again, all undefined terminology can be found in [169, Ch. 3].

**Theorem 57.** Let \( P \) be a finite poset, \( R \) be a commutative ring, and \( f, g : P \times P \to R \) be two incidence functions, that is, \( f(x,y) = 0 \) unless \( x \leq y \) in \( P \), the same being true for \( g \). Then

\[
\det_{x,y \in P} \left( \sum_{z \in P} f(z,x)g(z,y) \right) = \prod_{x \in P} f(x,x)g(x,x).
\]

The reader is referred to Section 3 of [6] for the explanation why this theorem implies Lindström’s.

### 5.9. Determinants for Compositions

Our next family of determinants consists of determinants of matrices the rows and columns of which are indexed by compositions. Recall that a composition of a non-negative integer \( n \) is a vector \((\alpha_1, \alpha_2, \ldots, \alpha_k)\) of non-negative integers such that \( \alpha_1 + \alpha_2 + \cdots + \alpha_k = n \), for some \( k \). For a fixed \( k \), let \( \mathcal{C}(n,k) \) denote the corresponding set of compositions of \( n \). While working on a problem in global optimisation, Brunat and Montes [28] discovered the following surprising determinant evaluation. It allowed them to show how to explicitly express a multivariable polynomial as a difference of convex functions. In the statement, we use standard multi-index notation: if \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_k) \) and \( \beta = (\beta_1, \beta_2, \ldots, \beta_k) \) are two compositions, we let

\[
\alpha^\beta := \alpha_1^{\beta_1} \alpha_2^{\beta_2} \cdots \alpha_k^{\beta_k}.
\]
Theorem 58. For any positive integers \( n \) and \( k \), we have
\[
\det_{\alpha, \beta \in \mathbb{C}(n, k)} (\alpha^{\beta}) = n^{(\frac{k}{k-1})^n + k - 1} \prod_{i=1}^{n-1} i^{n-i+1} (\frac{k}{k-1})^{n-i-1}.
\] (5.100)

However, computer experiments indicate that, in fact, a slightly more general statement is true.

Conjecture 59. For any positive integers \( n \) and \( k \), we have
\[
\det_{\alpha, \beta \in \mathbb{C}(n, k)} ((x + \alpha)^{\beta}) = (kx + n)^{\left(\frac{k}{k-1}\right)^n + k - 1} \prod_{i=1}^{n-1} i^{n-i+1} (\frac{k}{k-1})^{n-i-1},
\] (5.101)
where \( x \) is a variable, and \( x + \alpha \) is short for \( x + \alpha_1, x + \alpha_2, \ldots, x + \alpha_n \).

More computer experiments lead one to believe that there is also a binomial variant of this determinant evaluation. Extending our multi-index notation, let
\[
\begin{pmatrix} \alpha \\ \beta \end{pmatrix} := \begin{pmatrix} \alpha_1 \\ \beta_1 \end{pmatrix} \begin{pmatrix} \alpha_2 \\ \beta_2 \end{pmatrix} \cdots \begin{pmatrix} \alpha_k \\ \beta_k \end{pmatrix}.
\]

Conjecture 60. For any positive integers \( n \) and \( k \), we have
\[
\det_{\alpha, \beta \in \mathbb{C}(n, k)} \left( (x + \alpha + \beta)^{\beta} \right) = \frac{\prod_{i=0}^{n-1} (kx + n + k + i)^{\left(\frac{k+1}{k-1}\right)^i}}{\prod_{i=1}^{n} i^{(\frac{k}{k-1})^{i-1}}},
\] (5.102)
where \( x \) is a variable, and \( x + \alpha + \beta \) is short for \( x + \alpha_1 + \beta_1, x + \alpha_2 + \beta_2, \ldots, x + \alpha_k + \beta_k \).

It is possible that both conjectures can be proved by adapting the proof of Theorem 58 in [28] appropriately. I report that, if one naively replaces “compositions” by “integer partitions” in the above considerations, then the arising determinants do not have nice product formulae.

Another interesting determinant of a matrix with rows indexed by compositions appears in the work of Bergeron, Reutenauer, Rosas and Zabrocki [21, Theorem 4.8] on Hopf algebras of non-commutative symmetric functions. It was used there to show that a certain set of generators of non-commutative symmetric functions were algebraically independent. To state their determinant evaluation, we need to introduce some notation. Given a composition \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_k) \) of \( n \) with all summands \( \alpha_i \) positive, we let \( D(\alpha) = \{\alpha_1, \alpha_1 + \alpha_2, \ldots, \alpha_1 + \alpha_2 + \cdots + \alpha_{k-1}\} \). Furthermore, for two compositions \( \alpha \) and \( \beta \) of \( n \), we write \( \alpha \cup \beta \) for the (unique) composition \( \gamma \) of \( n \) with \( D(\gamma) = D(\alpha) \cup D(\beta) \). Finally, \( \alpha ! \) is short for \( \alpha_1! \alpha_2! \cdots \alpha_k ! \).

Theorem 61. Let \( \text{Comp}(n) \) denote the set of all compositions of \( n \) all summands of which are positive. Then
\[
\det_{\alpha, \beta \in \text{Comp}(n)} ((\alpha \cup \beta)!) = \prod_{\gamma \in \text{Comp}(n)} \prod_{\ell(\gamma) = 1}^{\ell(\gamma)} a_{\gamma_1},
\] (5.103)
where \(\ell(\gamma)\) is the number of summands (components) of the composition \(\gamma\), and where \(a_m\) denotes the number of indecomposable permutations of \(m\) (cf. [170, Ex. 5.13(b)]). These numbers can be computed recursively by \(a_1 = 1\) and

\[
a_n = n! - \sum_{i=1}^{n-1} a_i(n - 1)!, \quad n > 1.
\]

As explained in [21], one proves the theorem by factoring the matrix in (5.103) in the form \(CDC^t\), where \(C\) is the “incidence matrix” of “refinement of compositions,” and where \(D\) is a diagonal matrix. Thus, in particular, the LU-factorisation of the matrix is determined.

**5.10. Two partition determinants.** On the surface, integer partitions (see below for their definition) seem to be very closely related to compositions, as they can be considered as “compositions where the order of the summands is without importance.” However, experience shows that integer partitions are much more complex combinatorial objects than compositions. This may be the reason that the “composition determinants” from the preceding subsection do not seem to have analogues for integer partitions. Leaving aside this disappointment, here is a problem concerning a determinant of a matrix in which rows and columns are indexed by integer partitions. This determinant arose in work on *linear forms of values of the Riemann zeta function evaluated at positive integers*, although the traces of it have now been completely erased in the final version of the article [108]. (The symmetric function calculus in Section 12 of the earlier version [107] gives a vague idea where it may have come from.)

Recall that the power symmetric function of degree \(d\) in \(x_1, x_2, \ldots, x_k\) is given by \(x_1^d + x_2^d + \cdots + x_k^d\), and is denoted by \(p_d(x_1, x_2, \ldots, x_k)\). (See [113, Ch. 1 and 2], [122, Ch. 1] and [170, Ch. 7] for in-depth expositions of the theory of symmetric functions.) Then, while working on [108], Rivol and the author needed to evaluate the determinant

\[
\det_{\lambda, \mu \in \text{Part}(n, k)} \left( p_\lambda(\mu_1, \mu_2, \ldots, \mu_k) \right),
\]

where \(\text{Part}(n, k)\) is the set of integer partitions of \(n\) with at most \(k\) parts, that is, the set of all possibilities to write \(n\) as a sum of non-negative integers, \(n = \lambda_1 + \lambda_2 + \cdots + \lambda_k\), with \(\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_k \geq 0\), and where

\[
p_\lambda(x_1, x_2, \ldots, x_k) = p_{\lambda_1}(x_1, \ldots, x_k)p_{\lambda_2}(x_1, \ldots, x_k) \cdots p_{\lambda_k}(x_1, \ldots, x_k).
\]

Following the advice given in Section 2, we went to the computer and let it calculate the prime factorisations of the values of this determinant for small values of \(n\) and \(k\). Indeed, the prime factors turned out to be always small so that we were sure that a “nice” formula exists for the determinant. However, even more seems to be true. Recall that, in order to facilitate a proof of a (still unknown) formula, it is (almost) always a good idea to try to introduce more parameters (see [103, Sec. 2]). This is what we did. It led us to the following problem.

**Problem 62.** Find and prove the closed form evaluation of

\[
\det_{\lambda, \mu \in \text{Part}(n, k)} \left( p_\lambda(\mu_1 + X_1, \mu_2 + X_2, \ldots, \mu_k + X_k) \right),
\]

where \(X_1, X_2, \ldots, X_k\) are indeterminates.
While the problem is easy for $k = 1$ (in that case, it reduces to a special case of the Vandermonde determinant evaluation), we were not able to come even close to a solution in general. (As I already indicated, finally we managed to avoid the determinant evaluation in our work in [108].) Here are some values of the determinant (5.105) for special values of $n$ and $k$. For $n = k = 3$ we obtain

$$6 (X_1 - X_2 + 2)(X_1 - X_3 + 1)(X_2 - X_3 + 1)(X_1 + X_2 + X_3 + 3)^4,$$

for $n = 4$ and $k = 3$ we obtain

$$8 (X_1 - X_2 + 1)(X_1 - X_2 + 2)(X_1 - X_2 + 3)(X_1 - X_3 + 2) \times (X_2 - X_3 + 1)(X_1 + X_2 + X_3 + 4)^7,$$

for $n = 5$ and $k = 3$ we get

$$8 (X_1 - X_2 + 1)(X_1 - X_2 + 2)(X_1 - X_2 + 3)(X_1 - X_2 + 4)(X_1 - X_3 + 2) \times (X_1 - X_3 + 3)(X_2 - X_3 + 1)(X_2 - X_3 + 2)(X_1 + X_2 + X_3 + 5)^{11},$$

for $n = 6$ and $k = 3$ we get

$$576 (X_1 - X_2 + 1)(X_1 - X_2 + 2)^2(X_1 - X_2 + 3)^2(X_1 - X_2 + 4)(X_1 - X_2 + 5) \times (X_1 - X_3 + 1)(X_1 - X_3 + 2)(X_1 - X_3 + 3)(X_1 - X_3 + 4)(X_2 - X_3 + 1)^2 \times (X_2 - X_3 + 2)^2(X_1 + X_2 + X_3 + 6)^{16},$$

for $n = 4$ and $k = 4$ we get

$$192 (X_1 - X_2 + 1)(X_1 - X_2 + 2)(X_1 - X_2 + 3)(X_1 - X_3 + 2)(X_2 - X_3 + 1) \times (X_1 - X_4 + 1)(X_2 - X_4 + 1)(X_3 - X_4 + 1)(X_1 + X_2 + X_3 + X_4 + 4)^7$$

while for $n = 5$ and $k = 4$ we get

$$48 (X_1 - X_2 + 1)(X_1 - X_2 + 2)(X_1 - X_2 + 3)(X_1 - X_2 + 4)(X_1 - X_3 + 2) \times (X_1 - X_3 + 3)(X_2 - X_3 + 1)(X_2 - X_3 + 2)(X_1 - X_4 + 2) \times (X_2 - X_4 + 1)(X_3 - X_4 + 1)(X_1 + X_2 + X_3 + X_4 + 5)^{12}.$$

It is “therefore” evident that there will be one factor which is a power of $n + \sum_{i=1}^{k} X_i$, whereas the other factors will be of the form $X_1 - X_j + c_{i,j}$, again raised to some power.

Many of the latter factors can be “explained” in the following way: if $f(x, y)$ is a polynomial in $x$ and $y$ and if $\mu_1 + \mu_2 = \mu_1 + \nu_2$, then the difference

$$f(X_1 + \mu_1, X_2 + \mu_2) - f(X_2 + \nu_2, X_1 + \nu_1)$$

is clearly divisible by $X_1 + \mu_1 - X_2 - \nu_2$. Therefore, if $\mu$ and $\nu$ are two partitions in $\text{Part}(n, k)$ which differ only in two parts, subtraction of the column indexed by $\nu$ from the one indexed by $\mu$ in the determinant in (5.105) will show that $X_1 + \mu_1 - X_2 - \nu_2$ is a factor of the determinant. However, this simple fact does not explain all the factors of this type.

Concerning the other type of factor, Alain Lascoux (private communication) noticed that the precise power of $n + \sum_{i=1}^{k} X_i$ is the number of partitions of a non-negative integer which is at most $n - 1$ with at most $k$ parts (including the empty partition). (See the paragraph around (5.107) for his arguments establishing this claim.) More
concretely, if we denote this number by \( e_{n,k} \), the generating function of the numbers \( e_{n,k} \) is given by
\[
\sum_{n=1}^{\infty} e_{n,k} x^{n-1} = \frac{1}{1 - q^k} \prod_{t=1}^{k} \frac{1}{1 - q^t}.
\]

We remark that Problem 62 is equivalent to the same problem, but with the power symmetric functions \( p_t \) replaced by the Schur functions \( s_{\lambda} \), because the transition matrix between these two bases of symmetric functions is the character table of the symmetric group of the corresponding order (cf. [122, Ch. I, Sec. 7]), the determinant of which is known (see Theorem 64 below). The determinant with Schur functions has some advantages over the one with power symmetric functions since the former decomposes into a finer block structure. Alain Lascoux observed that, in fact, there seems to be a generalization of the Schur function determinant to Graßmannian Schubert polynomials, which contains another set of variables, \( Y_1, Y_2, \ldots, Y_{n+k-1} \). More precisely, given \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k) \), let \( \Psi_\lambda(X_1, X_2, \ldots, X_k; Y_1, Y_2, \ldots) \) denote the polynomial in the variables \( X_1, X_2, \ldots, X_k \) and \( Y_1, Y_2, \ldots, Y_{n+k-1} \), defined by (see [113, Sections 1.4 and 9.7; the order of the \( B_k \) should be reversed in (9.7.2) and analogous places])
\[
\Psi_\lambda(X_1, X_2, \ldots, X_k; Y_1, Y_2, \ldots) := \det_{1 \leq i,j \leq k} (S_{\lambda_i-i+j}(X_1, \ldots, X_k; Y_1, \ldots, Y_{n+k-1})),
\]
where the entries of the determinant are given by
\[
\sum_{m=0}^{\infty} S_m(X_1, \ldots, X_k; Y_1, \ldots, Y_l)x^m = \frac{\prod_{i=1}^{l} (1 - Y_i x)}{\prod_{i=1}^{k} (1 - X_i x)}.
\]
The Graßmannian Schubert polynomials \( \Psi_\lambda \) reduce to Schur functions when all the variables \( Y_i, i = 1, 2, \ldots, \) are put equal to 0. Given these definitions, Alain Lascoux poses the following problem.

**Problem 63.** Find and prove the closed form evaluation of
\[
\det_{\lambda \in \mathrm{Part}(n,k)} (\Psi_\lambda(\mu_1 + X_1, \mu_2 + X_2, \ldots; \mu_k + X_k; Y_1, Y_2, \ldots)) \quad (5.106)
\]
where \( X_1, X_2, \ldots, X_k, Y_1, Y_2, \ldots \) are indeterminates.

As for the evidence that there is indeed a closed product formula for this determinant, here is the determinant for \( n = 3 \) and \( k = 2 \),
\[
(X_1 - X_2 + 2)(X_1 + X_2 - Y_1 - Y_2 + 3)(X_1 + X_2 - Y_1 + Y_2 + 3)
\times (X_1 + X_2 - Y_2 - Y_3 + 3)(X_1 + X_2 - Y_1 - Y_4 + 3),
\]
and the following is the one for \( n = k = 3 \),
\[
(X_1 - X_2 + 2)(X_1 - X_3 + 1)(X_2 - X_3 + 1)
\times (X_1 + X_2 + X_3 - Y_1 - Y_2 - Y_3 + 3)(X_1 + X_2 + X_3 - Y_1 - Y_2 - Y_4 + 3)
\times (X_1 + X_2 + X_3 - Y_1 - Y_2 - Y_3 + 3)(X_1 + X_2 + X_3 - Y_1 - Y_2 - Y_5 + 3).
\]
One should note that the repeated factors of the form \( n + \sum_{i=1}^{k} X_i \) appearing in the factorisation of the determinant of Problem 62 become distinct under the presence of
the variables $Y_1, Y_2, \ldots, Y_{n+k-1}$. In fact, the precise observation of Lascoux cited above is that these factors are all factors of the form

$$n + \sum_{i=1}^{k} X_i - \sum_{i=1}^{k} Y_{\sigma(i)},$$

(5.107)

where $\sigma$ runs through all Graßmannian permutations, the descent of which (if existent) is at $k$, and which contain at most $n-1$ inversions. To see that this is the case, one uses the Monk formula for double Schubert polynomials in the case of Graßmannian Schubert polynomials (see [97]),

$$\left( \sum_{i=1}^{k} X_i - \sum_{i=1}^{k} Y_{\lambda_{k-i+1}+i} \right) \Psi_{\lambda} = \Psi_{\lambda+(1,0,0,\ldots)} + \sum_{\mu} \Psi_{\mu},$$

where $\Psi_{\lambda}$ is short for $\Psi_{\lambda}(X_1, X_2, \ldots, X_k; Y_1, Y_2, \ldots)$, and where the sum on the right-hand side is over all partitions $\mu$ of the same size as $\lambda+(1,0,0,\ldots)$ but lexicographically smaller. Clearly, by using this identity, appropriate row operations in the determinant (5.106) show that (5.107) is indeed one of its factors, the relation between $\sigma$ and $\lambda$ being $\sigma(i) = \lambda_{k-i+1} + i$, $i = 1, 2, \ldots, k$. Moreover, doing these row operations, and taking out the factors of the form (5.107), we may reduce the determinant (5.106) to a determinant of the same form, in which, however, the partitions $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k)$ run over all partitions of size at most $n$ with the additional property that $\lambda_1 = \lambda_2$ (instead of over all partitions from $\text{Part}(n, k)$). As it turns out, the determinant thus obtained is independent of the variables $Y_1, Y_2, \ldots, Y_{n+k-1}$. Indeed, if we expand each Schubert polynomial $\Psi_{\lambda}(\mu_1 + X_1, \mu_2 + X_2, \ldots, \mu_k + X_k; Y_1, Y_2, \ldots)$ in the determinant as a linear combination of Schur functions in $X_1, X_2, \ldots, X_k$ with coefficients being polynomials in the $Y_1, Y_2, \ldots, Y_{n+k-1}$, then, by also using that

$$S_1(\mu_1 + X_1; \mu_2 + X_2, \ldots, \mu_k + X_k) = n + \sum_{i=1}^{k} X_i$$

is independent of $\mu$, it is not difficult to see that one can eliminate all the $Y_i$s by appropriate row operations. Still, it seems that there remains a non-trivial task in order to come up with a complete solution to Problem 63 (implying a solution to Problem 62).

A few paragraphs above, we mentioned in passing another interesting determinant of a matrix the rows and columns of which are indexed by (integer) partitions: the determinant of the character table of the symmetric group $\mathfrak{S}_n$ (cf. [83, Cor. 6.5]). Since this is a classical and beautiful determinant evaluation which I missed to state in [103], I present it now in the theorem below. There, the notation $\lambda + n$ stands for “$\lambda$ is a partition of $n$.” For all undefined notation, I refer the reader to standard texts on the representation theory of symmetric groups, as for example [83, 84, 151].

---

30A permutation $\sigma$ in $\mathfrak{S}_{\infty}$ (the set of all permutations of the natural numbers $\mathbb{N}$ which fix all but a finite number of elements of $\mathbb{N}$) is called Graßmannian if $\sigma(i) < \sigma(i+1)$ for all $i$ except possibly for one, the latter being called the descent of $\sigma$ (see [121, p. 13]).
**Theorem 64.** For partitions $\lambda$ and $\rho$ of $n$, let $\chi^\lambda(\rho)$ denote the value of the irreducible character $\chi^\lambda$ evaluated at a permutation of cycle type $\rho$. Then

$$
\det_{\lambda,\rho^{n}}(\chi^\lambda(\rho)) = \prod_{\mu \vdash n} \prod_{i \geq 1} \mu_i.
$$

(5.108)

In words: the determinant of the character table of the symmetric group $S_n$ is equal to the products of all the parts of all the partitions of $n$. \hfill \Box

Further examples of nice determinant evaluations of tables of characters of representations of symmetric groups and their double covers can be found in [24, 134].

### 5.11 Elliptic determinant evaluations

In special functions theory there is currently a disease rapidly spreading, generalising the earlier mentioned $q$-disease (see Footnote 20). It could be called the “elliptic disease.” Recall that, during the $q$-disease, we replaced every positive integer $n$ by $1 + q + q^2 + \cdots + q^{n-1} = (1 - q^n)/(1 - q)$, and, more generally, shifted factorials $a(a+1)\cdots(a+k-1)$ by $q$-shifted factorials $(1 - \alpha)(1 - \alpha q)(1 - \alpha q^2)\cdots(1 - \alpha q^{k-1})$ (here, $\alpha$ takes the role of $q^r$, and one drops the powers of $1 - q$ in order notation). Doing this with some “ordinary” identity, we arrived (hopefully) at its $q$-analogue. Now, once infected by the elliptic disease, we would replace every occurrence of a term $1 - x$ (and, looking at the definition of $q$-shifted factorials, we can see that there will be many) by its elliptic analogue $\theta(x; p)$:

$$
\theta(x) = \theta(x; p) = \prod_{j=0}^{\infty} (1 - p^j x)(1 - p^{j+1}/x).
$$

Here, $p$ is a complex number with $|p| < 1$, which will be fixed throughout. Up to a trivial factor, $\theta(e^{2\pi i x}; e^{2\pi i r})$ equals the Jacobi theta function $\theta_1(x|\tau)$ (cf. [181]). Clearly, $\theta(x)$ reduces to $1 - x$ if $p = 0$.

At first sight, one will be sceptical if this is a fruitful thing to do. After all, for working with the functions $\theta(x)$, the only identities which are available are the (trivial) inversion formula

$$
\theta(1/x) = \frac{1}{x} \theta(x),
$$

(5.109)

the (trivial) quasi-periodicity

$$
\theta(px) = \frac{1}{x} \theta(x),
$$

(5.110)

and Riemann’s (highly non-trivial) addition formula (cf. [181, p. 451, Example 5])

$$
\theta(xy) \theta(x/y) \theta(u/v) \theta(u/v) - \theta(xy) \theta(x/v) \theta(u) \theta(u/y) = \frac{u}{y} \theta(yv) \theta(y/v) \theta(xu) \theta(x/u).
$$

(5.111)

Nevertheless, it has turned out recently that a surprising number of identities from the “ordinary” and from the “$q$-world” can be lifted to the elliptic level. This is particularly true for series of hypergeometric nature. We refer the reader to Chapter 11 of [66] for an account of the current state of the art in the theory of, as they are called now, elliptic hypergeometric series.

On the following pages, I give elliptic determinant evaluations a rather extensive coverage because, first of all, they were non-existent in [103] (with the exception of the mention of the papers [125, 126] by Milne), and, second, because I believe that the
“elliptic research” is a research direction that will further prosper in the next future and will have numerous applications in many fields, also outside of just special functions theory and number theory. I further believe that the determinant evaluations presented in this subsection will turn out to be as fundamental as the determinant evaluations in Sections 2.1 and 2.2 in [103]. For some of them this belief is already a fact. For example, determinant evaluations involving elliptic functions have come into the picture in the theory of multiple elliptic hypergeometric series, see [89, 139, 144, 145, 147, 168, 179]. They have also an important role in the study of Ruijsenaars operators and related integrable systems [75, 149]. Furthermore, they have recently found applications in number theory to the problem of counting the number of representations of an integer as a sum of triangular numbers [146].

Probably the first elliptic determinant evaluation is due to Frobenius [63, (12)]. This identity has found applications to Ruijsenaars operators [149], to multidimensional elliptic hypergeometric series and integrals [89], [139] and to number theory [146]. For a generalisation to higher genus Riemann surfaces, see [56, Cor. 2.19]. Amdeberhan [7] observed that it can be easily proved using the condensation method (see “Method 2” in Section 4).

**Theorem 65.** Let $x_1, x_2, \ldots, x_n$, $a_1, a_2, \ldots, a_n$ and $t$ be indeterminates. Then there holds

$$
\begin{align*}
\det_{1 \leq i,j \leq n} \left( \frac{\theta(ta_i x_j)}{\theta(t)} \frac{\theta(a_j x_i)}{\theta(t)} \right) &= \frac{\theta(t a_1 \cdots a_n x_1 \cdots x_n)}{\theta(t)} \prod_{1 \leq i,j \leq n} a_j x_j \frac{\theta(a_i/a_j)}{\theta(x_i/x_j)} \prod_{i,j=1}^n \theta(a_j x_i).
\end{align*}
$$

(5.112)

\[ \blacksquare \]

For $p = 0$ and $t \to \infty$, this determinant identity reduces to Cauchy’s evaluation (5.5) of the double alternant, and, thus, may be regarded as an “elliptic analogue” of the latter.

Olada [132, Theorem 1.1] has recently found an elliptic extension of Schur’s evaluation (5.7) of a Cauchy-type Pfaffian. His proof works by the Pfaffian version of the condensation method.

**Theorem 66.** Let $x_1, x_2, \ldots, x_n$, $t$ and $w$ be indeterminates. Then there holds

$$
\begin{align*}
\Pf_{1 \leq i,j \leq 2n} \left( \frac{\theta(x_j/x_i)}{\theta(x_i x_j)} \frac{\theta(tx_i x_j)}{\theta(t)} \frac{\theta(wx_i x_j)}{\theta(w)} \right) &= \frac{\theta(tx_1 \cdots x_{2n})}{\theta(t)} \frac{\theta(wx_1 \cdots x_{2n})}{\theta(w)} \prod_{1 \leq i,j \leq 2n} \theta(x_j/x_i) x_j \theta(x_i x_j).
\end{align*}
$$

(5.113)

\[ \blacksquare \]

The next group of determinant evaluations is from [148, Sec. 3]. As the Vandermonde determinant evaluation, or the other Weyl denominator formulae (cf. [103, Lemma 2]), are fundamental polynomial determinant evaluations, the evaluations in Lemma 67 below are equally fundamental in the elliptic domain as they can be considered as the elliptic analogues of the former. Indeed, Rosengren and Schlosser show that they imply
the Macdonald identities associated to affine root systems [120], which are the affine analogues of the Weyl denominator formulae. In particular, in this way they obtain new proofs of the Macdonald identities.

In order to conveniently formulate Rosengren and Schlosser’s determinant evaluations, we shall adopt the following terminology from [148]. For $0 < |p| < 1$ and $t \neq 0$, an $A_{n-1}$ theta function $f$ of norm $t$ is a holomorphic function for $x \neq 0$ such that

$$f(px) = \frac{(-1)^n}{tx^n} f(x). \quad (5.114)$$

Moreover, if $R$ denotes either of the root systems $B_n$, $B_n^\vee$, $C_n$, $C_n^\vee$, $BC_n$ or $D_n$ (see Footnote 25 and [78] for information on root systems), we call $f$ an $R$ theta function if

$$f(px) = \frac{1}{p^{n-1}x^{2n-1}} f(x), \quad f(1/x) = -\frac{1}{x} f(x), \quad R = B_n,$$

$$f(px) = \frac{1}{p^2 x^{2n}} f(x), \quad f(1/x) = -f(x), \quad R = B_n^\vee,$$

$$f(px) = \frac{1}{p^{n+1}x^{2n+2}} f(x), \quad f(1/x) = -f(x), \quad R = C_n,$$

$$f(px) = \frac{1}{p^{-1}x^{2n}} f(x), \quad f(1/x) = -\frac{1}{x} f(x), \quad R = C_n^\vee,$$

$$f(px) = \frac{1}{p^n x^{2n+1}} f(x), \quad f(1/x) = -\frac{1}{x} f(x), \quad R = BC_n,$$

$$f(px) = \frac{1}{p^{n-1}x^{2n-2}} f(x), \quad f(1/x) = f(x), \quad R = D_n.$$

Given this definition, Rosengren and Schlosser [148, Lemma 3.2] show that a function $f$ is an $A_{n-1}$ theta function of norm $t$ if and only if there exist constants $C$, $b_1, \ldots, b_n$ such that $b_1 \cdots b_n = t$ and

$$f(x) = C \theta(b_1 x) \cdots \theta(b_n x),$$

and for the other six cases, they show that $f$ is an $R$ theta function if and only if there exist constants $C$, $b_1, \ldots, b_{n-1}$ such that

$$f(x) = C \theta(x) \theta(b_1 x) \cdots \theta(b_{n-1} x) \theta(b_{n-1}/x), \quad R = B_n,$$

$$f(x) = C x^{-1} \theta(x^2; p^2) \theta(b_1 x) \theta(b_1/x) \cdots \theta(b_{n-1} x) \theta(b_{n-1}/x), \quad R = B_n^\vee,$$

$$f(x) = C x^{-1} \theta(x^2; p^2) \theta(b_1 x) \theta(b_1/x) \cdots \theta(b_{n-1} x) \theta(b_{n-1}/x), \quad R = C_n,$$

$$f(x) = C \theta(x; p^2) \theta(b_1 x) \theta(b_1/x) \cdots \theta(b_{n-1} x) \theta(b_{n-1}/x), \quad R = C_n^\vee,$$

$$f(x) = C \theta(x) \theta(p^2 x^2; p^2) \theta(b_1 x) \theta(b_1/x) \cdots \theta(b_{n-1} x) \theta(b_{n-1}/x), \quad R = BC_n,$$

$$f(x) = C \theta(b_1 x) \theta(b_1/x) \cdots \theta(b_{n-1} x) \theta(b_{n-1}/x), \quad R = D_n,$$

where $\theta(x) = \theta(x; p)$.

If one puts $p = 0$, then an $A_{n-1}$ theta function of norm $t$ becomes a polynomial of degree $n$ such that the reciprocal of the product of its roots is equal to $t$. Similarly, if one puts $p = 0$, then a $D_n$ theta function becomes a polynomial in $(x + 1/x)$ of degree $n$. This is the specialisation of some of the following results which is relevant for obtaining the earlier Lemmas 16–20.
The elliptic extension of the Weyl denominator formulae is the following formula. (See [148, Prop. 3.4].)

**Lemma 67.** Let \( f_1, \ldots, f_n \) be \( A_{n-1} \) theta functions of norm \( t \). Then,
\[
\det_{1 \leq i, j \leq n} (f_j(x_i)) = C \, W_{A_{n-1}}(x),
\]
(5.115)
for some constant \( C \), where
\[
W_{A_{n-1}}(x) = \theta(tx_1 \cdots x_n) \prod_{1 \leq i < j \leq n} x_j \theta(x_i/x_j).
\]
Moreover, if \( R \) denotes either \( B_n, B_n', C_n, C_n', BC_n \) or \( D_n \) and \( f_1, \ldots, f_n \) are \( R \) theta functions, we have
\[
\det_{1 \leq i, j \leq n} (f_j(x_i)) = C \, W_R(x),
\]
(5.116)
for some constant \( C \), where
\[
\begin{align*}
W_{B_n}(x) &= \prod_{i=1}^n \theta(x_i) \prod_{1 \leq i < j \leq n} x_j^{-1} \theta(x_i x_j) \theta(x_i/x_j), \\
W_{B_n'}(x) &= \prod_{i=1}^n x_i^{-1} \theta(x_i^2; p^2) \prod_{1 \leq i < j \leq n} x_j^{-1} \theta(x_i x_j) \theta(x_i/x_j), \\
W_{C_n}(x) &= \prod_{i=1}^n x_i^{-1} \theta(x_i^2) \prod_{1 \leq i < j \leq n} x_j^{-1} \theta(x_i x_j) \theta(x_i/x_j), \\
W_{C_n'}(x) &= \prod_{i=1}^n \theta(x_i; p^2) \prod_{1 \leq i < j \leq n} x_j^{-1} \theta(x_i x_j) \theta(x_i/x_j), \\
W_{BC_n}(x) &= \prod_{i=1}^n \theta(x_i) \theta(px_i^2; p^2) \prod_{1 \leq i < j \leq n} x_j^{-1} \theta(x_i x_j) \theta(x_i/x_j), \\
W_{D_n}(x) &= \prod_{1 \leq i < j \leq n} x_i^{-1} \theta(x_i x_j) \theta(x_i/x_j).
\end{align*}
\]

\( \Box \)

Rosengren and Schlosser show in [148, Prop. 6.1] that the famous Macdonald identities for affine root systems [120] are equivalent to special cases of this lemma. We state the corresponding results below.

**Theorem 68.** The following determinant evaluations hold:
\[
\det_{1 \leq i, j \leq n} \left( x_i^{j-1} \theta((-1)^{n-1} p^{j-1} x_i^n; p^n) \right) = \frac{(p;p)_\infty^n}{(p^2; p^n)_\infty^n} W_{A_{n-1}}(x),
\]
\[
\det_{1 \leq i, j \leq n} \left( x_i^{j-n} \theta(p^{j-1} x_i^{2n-1}; p^{2n-1}) - x_i^{n+1-j} \theta(p^{j-1} x_i^{1-2n}; p^{2n-1}) \right)
\]
\[
= \frac{2(p;p)_\infty^n}{(p^{2n-1}; p^{2n-1})_\infty^n} W_{B_n}(x),
\]
\[
\begin{aligned}
\det_{1 \leq i, j \leq n} & \left( x_i^{j-n-1} \theta(p^{j-1} x_i^{2n}; p^{2n}) - x_i^{n+1-j} \theta(p^{j-1} x_i^{-2n}; p^{2n}) \right) \\
& = \frac{2(p^2; p^2)_{\infty} (p; p)^{n-1}}{(p^{2n}; p^{2n})_{\infty}} W_{n_i}(x), \\
\det_{1 \leq i, j \leq n} & \left( x_i^{j-n-1} \theta(-p^j x_i^{2n+2}; p^{2n+2}) - x_i^{n+1-j} \theta(-p^j x_i^{-2n-2}; p^{2n+2}) \right) \\
& = \frac{(p; p)^n}{(p^{2n+2}; p^{2n+2})_{\infty}} W_{C_\eta}(x), \\
\det_{1 \leq i, j \leq n} & \left( x_i^{j-n} \theta(-p^j x_i^{2n}; p^{2n}) - x_i^{n+1-j} \theta(-p^j x_i^{-2n}; p^{2n}) \right) \\
& = \frac{(p^2; p^2)_{\infty} (p; p)^{n-1}}{(p^{2n}; p^{2n})_{\infty}} W_{C_\eta}(x), \\
\det_{1 \leq i, j \leq n} & \left( x_i^{j-n} \theta(-p^j x_i^{2n+1}; p^{2n+1}) - x_i^{n+1-j} \theta(-p^j x_i^{-2n-1}; p^{2n+1}) \right) \\
& = \frac{(p^2; p^2)_{\infty} (p; p)^n}{(p^{2n+1}; p^{2n+1})_{\infty}} W_{B_{C_\eta}}(x), \\
\det_{1 \leq i, j \leq n} & \left( x_i^{j-n} \theta(-p^j x_i^{2n-2}; p^{2n-2}) + x_i^{n-j} \theta(-p^j x_i^{-2n-2}; p^{2n-2}) \right) \\
& = \frac{4(p; p)^n}{(p^{2n-2}; p^{2n-2})_{\infty}} W_{D_\eta}(x), \quad n \geq 2.
\end{aligned}
\]

Historically, aside from Frobenius’ elliptic Cauchy identity (5.112), the subject of elliptic determinant evaluations begins with Warnaar’s remarkable paper [179]. While the main subject of this paper is elliptic hypergeometric series, some elliptic determinant evaluations turn out to be crucial for the proofs of the results. Lemma 5.3 from [179] extends one of the basic determinant lemmas listed in [103], namely [103, Lemma 5], to the elliptic world, to which it reduces in the case \( p = 0 \). We present this important elliptic determinant evaluation in the theorem below.

**Theorem 69.** Let \( x_1, x_2, \ldots, x_n, a_1, a_2, \ldots, a_n \) be indeterminates. For each \( j = 1, \ldots, n \), let \( P_j(x) \) be a \( D_j \) theta function. Then there holds

\[
\begin{aligned}
\det_{1 \leq i, j \leq n} & \left( P_j(x_i) \prod_{k=j+1}^n \theta(a_k x_i) \theta(a_k / x_i) \right) \\
& = \prod_{k=1}^n P_i(a_k) \prod_{1 \leq i < j \leq n} a_j x_j^{-1} \theta(x_j x_i) \theta(x_j / x_i). \quad (5.117)
\end{aligned}
\]

Warnaar used this identity to obtain a summation formula for a multidimensional elliptic hypergeometric series. Further related applications may be found in [144, 145, 147, 168]. The relevant special case of the above theorem is the following (see [179,
Cor. 5.4]. It is the elliptic generalisation of [103, Theorem 28]. In the statement, we use the notation
\[(a; q, p)_n = \theta(a; p)\theta(aq; p) \cdots \theta(aq^{n-1}; p),\]  
which extends the notation for \(q\)-shifted factorials to the elliptic world.

**Theorem 70.** Let \(X_1, X_2, \ldots, X_n, A, B\) and \(C\) be indeterminates. Then, for any non-negative integer \(n\), there holds
\[
\det_{1 \leq i, j \leq n} \left( \frac{(AX_i; q, p)_{n-j} (AC/X_i; q, p)_{n-j}}{(BX_i; q, p)_{n-j} (BC/X_i; q, p)_{n-j}} \right) \\
= (Aq)_{(2)}^{(n)} \prod_{1 \leq i < j \leq n} X_j \theta(X_i/X_j) \theta(C/X_iX_j) \prod_{i=1}^{n} \frac{(B/A; q, p)_{i-1} (ABCq^{2n-2i}; q, p)_{i-1}}{(BX_i; q, p)_{n-1} (BC/X_i; q, p)_{n-1}}.
\]  
(5.119) \]

\[\square\]

Theorem 29 from [103], which is slightly more general than [103, Theorem 28], can also be extended to an elliptic theorem by suitably specialising the variables in Theorem 69.

**Theorem 71.** Let \(X_1, X_2, \ldots, X_n, Y_1, Y_2, \ldots, Y_n, A\) and \(B\) be indeterminates. Then, for any non-negative integer \(n\), there holds
\[
\det_{1 \leq i, j \leq n} \left( \frac{(X_j; q, p)_j (AY_j/X_i; q, p)_j}{(BX_i; q, p)_j (AB/X_i; q, p)_j} \right) \\
= q^{2n\binom{n}{2}} (AB)_{(2)}^{(n)} \prod_{1 \leq i < j \leq n} \theta(X_jX_i/A) \theta(X_j/X_i) \times \prod_{i=1}^{n} \frac{(ABY_iq^{i-2}; q, p)_{i-1} (Y_i/Bq^{i-1}; q, p)_{i-1}}{(BX_i; q, p)_{n-1} (AB/X_i; q, p)_{n-1}}.
\]  
(5.120) \]

\[\square\]

Another, very elegant, special case of Theorem 69 is the following elliptic Cauchy-type determinant evaluation. It was used by Rains [139, Sec. 3] in the course of deriving a \(BC_n \leftrightarrow BC_m\) integral transformation.

**Lemma 72.** Let \(x_1, x_2, \ldots, x_n\) and \(a_1, a_2, \ldots, a_n\) be indeterminates. Then there holds
\[
\det_{1 \leq i, j \leq n} \left( \frac{1}{\theta(a_jx_i) \theta(a_i/x_i)} \right) = \prod_{1 \leq i < j \leq n} a_jx_j^{-1} \theta(x_jx_i) \theta(x_j/x_i) \theta(a_ia_j) \theta(a_i/a_j) \prod_{i,j=1}^{n} \theta(a_jx_i) \theta(a_i/x_i).
\]  
(5.121) \]

\[\square\]

The remaining determinant evaluations in the current subsection, with the exception of the very last one, are all due to Rosengren and Schlosser [148]. The first one is a further (however non-obvious) consequence of Theorem 69 (see [148, Cor. 4.3]). Two related determinant evaluations, restricted to the polynomial case, were applied in [154] and [156] to obtain multidimensional matrix inversions that played a major role in the derivation of new summation formulae for multidimensional basic hypergeometric series.
Theorem 73. Let \(x_1, x_2, \ldots, x_n, a_1, a_2, \ldots, a_{n+1}\), and \(b\) be indeterminates. For each \(j = 1, \ldots, n+1\), let \(P_j(x)\) be a \(D_j\) theta function. Then there holds

\[
P_{n+1}(b) \det_{1 \leq i,j \leq n} \left( P_j(x_i) \prod_{k=j+1}^{n+1} \left( \theta(a_k x_i) \theta(a_k / x_i) \right) \right)
- \frac{P_{n+1}(x_i)}{P_{n+1}(b)} P_j(b) \prod_{k=j+1}^{n+1} \left( \theta(a_k b) \theta(a_k / b) \right)
= \prod_{i=1}^{n+1} P_i(a_i) \prod_{1 \leq i < j \leq n+1} a_j x_j^{-1} \theta(x_j x_i) \theta(x_j / x_i), \quad (5.122)
\]

where \(x_{n+1} = b\).

The next determinant evaluation is Theorem 4.4 from [148]. It generalises another basic determinant lemma listed in [103], namely Lemma 6 from [103], to the elliptic case. It looks as if it is a limit case of Warnaar’s in Theorem 69. However, limits are very problematic in the elliptic world, and therefore it does not seem that Theorem 69 implies the theorem below. For a generalisation in a different direction than Theorem 69 see [174, Appendix B] (cf. also [148, Remark 4.6]).

Theorem 74. Let \(x_1, x_2, \ldots, x_n, a_1, a_2, \ldots, a_n\), and \(t\) be indeterminates. For each \(j = 1, \ldots, n\), let \(P_j(x)\) be an \(A_{j-1}\) theta function of norm \(ta_1 \cdots a_j\). Then there holds

\[
\det_{1 \leq i,j \leq n} \left( P_j(x_i) \prod_{k=j+1}^{n} \theta(a_k x_i) \right)
= \frac{\theta(t a_1 \cdots a_n x_1 \cdots x_n)}{\theta(t)} \prod_{i=1}^{n} P_i(1/a_i) \prod_{1 \leq i < j \leq n} a_j x_j \theta(x_j / x_i). \quad (5.123)
\]

As is shown in [148, Cor. 4.8], this identity implies the following determinant evaluation.

Theorem 75. Let \(x_1, x_2, \ldots, x_n, a_1, a_2, \ldots, a_{n+1}\) and \(b\) be indeterminates. For each \(j = 1, \ldots, n+1\), let \(P_j(x)\) be an \(A_{j-1}\) theta function of norm \(ta_1 \cdots a_j\). Then there holds

\[
P_{n+1}(b) \det_{1 \leq i,j \leq n} \left( P_j(x_i) \prod_{k=j+1}^{n+1} \theta(a_k x_i) - \frac{P_{n+1}(x_i)}{P_{n+1}(b)} P_j(b) \prod_{k=j+1}^{n+1} \theta(a_k b) \right)
= \frac{\theta(t a_1 \cdots a_{n+1} x_1 \cdots x_n)}{\theta(t)} \prod_{i=1}^{n+1} P_i(1/a_i) \prod_{1 \leq i < j \leq n+1} a_j x_j \theta(x_j / x_i), \quad (5.124)
\]

where \(x_{n+1} = b\).

By combining Lemma 72 and Theorem 74, a determinant evaluation similar to the one in Theorem 73, but different, is obtained in [148, Theorem 4.9].
Theorem 76. Let $x_1, x_2, \ldots, x_n, a_1, a_2, \ldots, a_n$, and $c_1, \ldots, c_{n+2}$ be indeterminates. For each $j = 1, \ldots, n$, let $P_j(x)$ be an $A_{j-1}$ theta function of norm $(c_1 \cdots c_{n+2} a_{j+1} \cdots a_n)^{-1}$. Then there holds

\[
\det_{1 \leq i, j \leq n} \left( x_i^{n-j} P_j(x_i) \prod_{k=1}^{n+2} \theta(c_k x_i) \prod_{k=j+1}^{n} \theta(a_k x_i) \right. \\
- x_i^{n+1} P_j(x_i^{-1}) \prod_{k=1}^{n+2} \theta(c_k x_i^{-1}) \prod_{k=j+1}^{n} \theta(a_k x_i^{-1}) \\
= \frac{a_1 \cdots a_n}{x_1 \cdots x_n \theta(c_1 \cdots c_{n+2} a_1 \cdots a_n)} \prod_{i=1}^{n} P_i(1/a_i) \\
\times \prod_{1 \leq i < j \leq n+2} \theta(c_i c_j) \prod_{i=1}^{n} \theta(x_i^{n-j}) \prod_{1 \leq i < j \leq n} a_j x_i^{-1} \theta(x_i x_j) \theta(x_i / x_j). \tag{5.125}
\]

The last elliptic determinant evaluation which I present here is a surprising elliptic extension of a determinant evaluation due to Andrews and Stanton [13, Theorem 8] (see [103, Theorem 42]) due to Warnaar [179, Theorem 4.17]. It is surprising because in the former there appear $q$-shifted factorials and $q^2$-shifted factorials at the same time, but nevertheless there exists an elliptic analogue, and to obtain it one only has to add to the $p$ everywhere in the shifted factorials to convert them to elliptic ones.

Theorem 77. Let $x$ and $y$ be indeterminates. Then, for any non-negative integer $n$, there holds

\[
\det_{0 \leq i, j \leq n-1} \left( \frac{(y/x^q; q^2, p)_{i+j}}{(q/y x q^2; q^2, p)_{i+j}} \frac{(q/x^q q^{2i+4}; q^2, p)_{i+j}}{(1/x^q q^{2i+4}; q^2, p)_{i+j}} \right) \\
= \prod_{i=0}^{n-1} \frac{(x^2 q^{2i+1}; q, p)_{i+j} (x^2 y q^2; q^2, p)_{i+j} (y x q^{2i+1}; q, p)_{i+j}}{(x^2 q^{2i+2}; q^2, p)_{i+j} (y x q^2; q^2, p)_{i+j} (x q^{2i+1}; q, p)_{i+j} (x q^{2i+2}; q, p)_{i+j}}. \tag{5.126}
\]

In closing this final subsection, I remind the reader that, as was already said before, many Hankel determinant evaluations involving elliptic functions can be found in [125] and [126].

Acknowledgments

I would like to thank Anders Björner and Richard Stanley, and the Institut Mittag-Leffler, for giving me the opportunity to work in a relaxed and inspiring atmosphere during the “Algebraic Combinatorics” programme in Spring 2005 at the Institut, without which this article would never have reached its present form. Moreover, I am extremely grateful to Dave Saunders and Zhendong Wan who performed the LinBox computations of determinants of size 3840, without which it would have been impossible for me to formulate Conjectures 46–48 and 50. Furthermore I wish to thank Greg Kuperberg, Yuval Roichman, Hjalmar Rosengren, Michael Schlosser, Guoce Xin, and
especially Alain Lascoux, for the many useful comments and discussions which helped to improve the contents of this paper considerably.
